1. Introduction. LossLess is a programming language and environment similar to scheme. This document describes the implementation of a LossLess run-time written in C and LossLess itself will be described elsewhere. In unambiguous cases LossLess may be used to refer specifically to the implementation.

This code started off its life as s9fes by Nils M. Holm¹. After a few iterations including being briefly ported to perl this rather different code is the result, although at its core it follows the same design.

All of the functions, variables, etc. used by LossLess are exported via lossless.h, even those which are nominally internal. Although this is not best practice for a library it makes this document less repetetive and facilitates easier testing.

2. The structure is of a virtual machine with a single accumulator register and a stack. There is a single entry point to the VM—*interpret*—called after parsed source code has been put into the accumulator, where the result will also be left.

```
⟨System headers 4⟩
⟨Repair the system headers 526⟩
⟨Preprocessor definitions⟩
⟨Complex definitions & macros 146⟩
⟨Type definitions 5⟩
⟨Function declarations 8⟩
⟨Global variables 6⟩
```

3. \langle Global initialisation $_3\rangle$ \equiv /* This is located here to name it in full for CWEB's benefit */ See also sections 33, 69, 80, 103, 114, 184, and 197.

This code is cited in section 97.

This code is used in section 98.

¹ http://t3x.org/s9fes/

4. LossLess has few external dependencies, primarily *stdio* and *stdlib*, plus some obvious memory mangling functions from the C library there's no point in duplicating.

 $\mathtt{LL_ALLOCATE}$ allows us to define a wrapper around reallocarray which is used to make it artificially fail during testing.

```
⟨System headers 4⟩ ≡
#include <ctype.h>
#include <limits.h>
#include <setjmp.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h> /* for memset */
#include <sys/types.h>
#include 
#include <sys/types.h>
#include <sys/types.h>
#include 
#define LL_ALLOCATE reallocarray
#endif
This code is used in sections 1, 2, and 224.
```

5. The *boolean* and *predicate* C types are used to distinguish between *boolean*-returning functions reporting C truth (0 or 1) or *predicate*-returning functions reporting LossLess truth (FALSE or TRUE). Otherwise-untyped C macros always report C truth.

```
#define bfalse 0
#define btrue 1
⟨Type definitions 5⟩ ≡
typedef int32_t cell;
typedef int boolean;
typedef cell predicate;
See also sections 90, 148, and 229.
This code is used in sections 1 and 2.
```

6. Error Handling. Everything needs to be able to report errors and so even though the details will make little sense without a more complete understanding of LossLess the code and data to handle them come first in full.

When the VM begins it establishes two jump buffers. To understand jump buffers it's necessary to understand how C's stack works and we have enough stacks already.

The main thing to know is that whenever C code calls a function it grows its own stack with the caller's return address. When *setjmp* is called the position in this stack is saved. When jumping back to that position with *longjmp*, anything which has been added to C's stack since the corresponding call to *setjmp* is discarded which has the effect of returning to exactly the point in the program where the corresponding *setjmp* was called, this time with a non-zero return value (the value that was given as an argument to *longjmp*; this facility is not used by LossLess for anything and it always sends 1).

The other thing that you don't need to know is that sometimes C compilers can make the previous paragraph a tissue of lies.

```
#define ERR_UNIMPLEMENTED "unimplemented"
#define error(x,d) error\lim p((x), NIL, (d))
#define ex_id car
#define ex_detail cdr
\langle \text{Global variables 6} \rangle \equiv
  volatile boolean Error\_Handler = bfalse;
  jmp_buf Goto_Begin;
  jmp_buf Goto_Error;
See also sections 12, 19, 25, 30, 47, 56, 66, 78, 91, 93, 101, 112, 150, 167, 182, 196, 222, 225, and 240.
This code is used in section 2.
7. \langle Externalised global variables 7\rangle \equiv
  extern volatile boolean Error_Handler;
  extern jmp_buf Goto_Begin;
  extern jmp_buf Goto_Error;
See also sections 13, 20, 26, 31, 42, 48, 57, 67, 79, 92, 94, 102, 113, 149, 168, 183, 223, 226, and 241.
This code is used in section 1.
8. \langle Function declarations 8 \rangle \equiv
  void ll_noreturn error_imp(char *, cell, cell);
  void warn(\mathbf{char} *, \mathbf{cell});
See also sections 14, 22, 27, 36, 43, 51, 59, 70, 73, 81, 88, 97, 104, 109, 115, 137, 169, 208, 230, 235, 239, 246, 489, and 519.
This code is used in sections 1 and 2.
```

9. Raised errors may either be a C-'string' when raised by an internal process or a *symbol* when raised at run-time.

If an error handler has been established then the *id* and *detail* are promoted to an *exception* object and the handler entered.

```
void error_imp(char *message, cell id, cell detail)
{
  int len;
  char wbuf[BUFFER\_SEGMENT] = \{0\};
  if (\neg null\_p(id)) {
    message = symbol\_store(id);
    len = symbol\_length(id);
  else len = strlen(message);
                          /* TODO: Save Acc or rely on id being it? */
  if (Error_Handler) {
    vms_push(detail);
    if (null_p(id)) id = sym(message);
    Acc = atom(id, detail, FORMAT_EXCEPTION);
    vms\_clear();
    longjmp(Goto\_Error, 1);
  write_form(detail, wbuf, BUFFER_SEGMENT, 0);
  printf("UNHANDLED_ERROR:__");
  for (; len --; message ++) putchar(*message);
  longjmp(Goto_Begin, 1);
}
```

10. Run-time errors are raised by the OP_ERROR opcode which passes control to *error_imp* (and never returns). The code which compiles **error** to emit this opcode comes later after the compiler has been defined.

11. We additionally define warn here because where else is it going to go?
 void warn(char *message, cell detail)
 {
 char wbuf[BUFFER_SEGMENT] = {0};
 write_form(detail, wbuf, BUFFER_SEGMENT, 0);
 printf("WARNING: _\%s: _\%s\n", message, wbuf);

 $^{^1}$ C does not have strings, it has pointers to memory buffers that probably contain ASCII and might also happen to have a Λ in them somewhere.

12. Memory Management. The most commonly used data type in lisp-like languages is the *pair*, also called a "cons cell" for histerical raisins, which is a datum consisting of two equally-sized halves. For reasons that don't bear thinking about they are called the *car* for the "first" half and the *cdr* for the "second" half. In this code & document, **cell** refers to each half of a *pair*. **cell** is not used to refer to a whole cons cell in order to avoid confusion.

A pair in LossLess is stored in 2 equally-sized areas of memory. On 64-bit x86 implementations, which are all I'm considering at the moment, each half is 32 bits wide. Each pair additionally has an 8 bit tag (1 byte) associated with it, stored in a third array.

Internally a *pair* is represented by an offset into these memory areas. Negative numbers are therefore available for a few global constants.

The pair's tag is treated as a bitfield. The garbage collector uses two bits (TAG_MARK and TAG_STATE). The other 6 bits are used to identify what data is stored in the **cells**.

```
/* Not \Lambda, but not nil_p/nil? either */
#define NIL -1
\#define FALSE -2
                           /* Yes, */
                         /* really. */
#define TRUE -3
#define END_OF_FILE -4
                                 /* stdio has EOF */
#define VOID -5
#define UNDEFINED
#define TAG_NONE
#define TAG_MARK
                               /* GC mark bit */
                                /* GC state bit */
#define TAG_STATE
                        #20
                                 /* CAR is a pair */
#define TAG_ACARP
#define TAG_ACDRP #10
                                 /* CDR is a pair */
                                  /* Mask lower 6 bits */
#define TAG_FORMAT #3f
#define HEAP_SEGMENT #8000
\langle \text{Global variables } 6 \rangle + \equiv
  \operatorname{cell} *CAR = \Lambda;
  \mathbf{cell} * CDR = \Lambda;
  char *TAG = \Lambda;
  cell Cells\_Free = NIL;
  int Cells\_Poolsize = 0;
  int Cells_Segment = HEAP_SEGMENT;
      \langle Externalised global variables 7\rangle + \equiv
  extern cell *CAR, *CDR, Cells_Free;
  extern char *TAG;
  extern int Cells_Poolsize, Cells_Segment;
     \langle Function declarations \rangle + \equiv
```

void new_cells_segment(void);

6

```
15. \langle Pre-initialise Small\_Int & other gc-sensitive buffers 15 \rangle \equiv free (CAR); free (CDR); free (TAG); CAR = CDR = \Lambda; TAG = \Lambda; Cells\_Free = NIL; Cells\_Poolsize = 0; Cells\_Poolsize = 0; Cells\_Segment = HEAP\_SEGMENT; See also sections 23, 28, 34, 50, 60, 68, 96, 171, and 228. This code is used in section 98.
```

16. The pool is spread across CAR, CDR and TAG and starts off with a size of zero cells, growing by Cells_Segment cells each time it's enlarged. When the heap is enlarged newly allocated memory is set to zero and the segment size set to half of the total pool size.

```
#define ERR_OOM "out-of-memory"
#define ERR_OOM_P(p) do { if ((p) \equiv \Lambda) error (ERR_OOM, NIL); } while (0)
#define ERR_DOOM_P(p,d) do { if ((p) \equiv \Lambda) error (ERR_OOM, (d)); } while (0)
#define enlarge\_pool(p, m, t) do
           void *n;
           n = LL\_ALLOCATE((p), (m), sizeof(t));
           ERR\_OOM\_P(n);
           (p) = n;
         while (0)
  void new_cells_segment(void)
    enlarge\_pool(CAR, Cells\_Poolsize + Cells\_Segment, cell);
    enlarge\_pool(CDR, Cells\_Poolsize + Cells\_Segment, cell);
    enlarge\_pool(TAG, Cells\_Poolsize + Cells\_Segment, char);
    bzero(CAR + Cells\_Poolsize, Cells\_Segment * sizeof(cell));
    bzero(CDR + Cells\_Poolsize, Cells\_Segment * sizeof(cell));
    bzero(TAG + Cells\_Poolsize, Cells\_Segment * sizeof(char));
    Cells\_Poolsize += Cells\_Segment;
    Cells\_Segment = Cells\_Poolsize/2;
  }
```

17. Preprocessor directives provide precidates to interrogate a pair's tag and find out what it is. Although not all of these cXr macros are used they are all defined here for completeness (and it's easier than working out which ones really are needed).

```
#define special_p(p) ((p) < 0)

```

8

18. Both atoms and cons cells are stored in pairs. The lower 6 bits of the tag define the format of data stored in that pair. The atoms are grouped into three types depending on whether both cells point to another pair, whether only the cdr does, or whether both cells are opaque. From this we obtain the core data types.

```
#define FORMAT_CONS (TAG_ACARP | TAG_ACDRP | #00)
#define FORMAT_APPLICATIVE (TAG_ACARP | TAG_ACDRP | #01)
#define FORMAT_OPERATIVE (TAG_ACARP | TAG_ACDRP | #02)

```

19. Allocating a new *pair* may require garbage collection to be performed. If the data being put into either half of the new *pair* is itself a *pair* it may be discarded by the collector. To avoid this happening the data are saved into preallocated temporary storage while a new *pair* is being located.

```
⟨Global variables 6⟩ +≡
cell Tmp_CAR = NIL;
cell Tmp_CDR = NIL;
20. ⟨Externalised global variables 7⟩ +≡
extern cell Tmp_CAR, Tmp_CDR;
21. ⟨Protected Globals 21⟩ ≡
& Tmp_CAR, & Tmp_CDR,
See also sections 32, 49, 58, 95, 170, and 227.
This code is used in section 41.
22. ⟨Function declarations 8⟩ +≡
cell atom(cell, cell, char);
23. ⟨Pre-initialise Small_Int & other gc-sensitive buffers 15⟩ +≡
Tmp_CAR = Tmp_CDR = NIL;
```

```
24. #define cons(a, d) atom((a), (d), FORMAT_CONS)
  cell atom(cell ncar, cell ncdr, char ntag)
    \mathbf{cell} \ r;
    if (null\_p(Cells\_Free)) {
      if (ntag \& TAG\_ACARP) Tmp\_CAR = ncar;
      if (ntag \& TAG\_ACDRP) Tmp\_CDR = ncdr;
      if (gc() \le (Cells\_Poolsize/2)) {
         new\_cells\_segment();
         gc();
       Tmp\_CAR = Tmp\_CDR = NIL;
    r = Cells\_Free;
    Cells\_Free = cdr(Cells\_Free);
    car(r) = ncar;
    cdr(r) = ncdr;
    tag(r) = ntag;
    return r;
```

25. Vectors. A *vector* stores a contiguous sequence of **cells**, each referring to a *pair* on the heap. Unlike *pairs vectors* are compacted during garbage collection to avoid fragmentation.

Storage is largely the same as **cells** except for how the free pointer is maintained: an index into the next unused **cell** in VECTOR.

```
\langle \text{Global variables } 6 \rangle + \equiv
  \mathbf{cell} * VECTOR = \Lambda;
  int Vectors\_Free = 0;
  int Vectors\_Poolsize = 0;
  int Vectors\_Segment = HEAP\_SEGMENT;
26. \langle Externalised global variables 7\rangle + \equiv
  extern cell *VECTOR;
  extern int Vectors_Free, Vectors_Poolsize, Vectors_Segment;
      \langle Function declarations \rangle + \equiv
  void new_vector_segment(void);
     \langle \text{Pre-initialise } Small\_Int \& \text{ other gc-sensitive buffers } 15 \rangle + \equiv
  free(VECTOR);
  \mathtt{VECTOR} = \Lambda;
   Vectors\_Free = Vectors\_Poolsize = 0;
   Vectors\_Segment = \texttt{HEAP\_SEGMENT};
29.
     void new_vector_segment(void)
  {
     \mathbf{cell} * new\_vector;
     new\_vector = LL\_ALLOCATE(VECTOR, Vectors\_Poolsize + Vectors\_Segment, sizeof(cell));
     ERR_0OM_P(new_vector);
     bzero(new\_vector + Vectors\_Poolsize, Vectors\_Segment * sizeof(cell));
     VECTOR = new\_vector;
     Vectors\_Poolsize += Vectors\_Segment;
     Vectors\_Segment = Vectors\_Poolsize/2;
```

30. When a pair holds a vector its tag is FORMAT_VECTOR, the car is used by the garbage collecter and the cdr is an index into VECTOR.

Each *vector* contains 2 additional pieces of metadata (which are **above** the index), the length of the *vector* and a reference back to the *pair* holding the *vector*.

A *vector* of length 0 is treated as a global constant akin to NIL but it must be stored in a variable and created during initialisation.

 $vector_index(r) = 0;$

for $(i = 0; i \le size; i++)$ $vector_ref(r, i) = fill;$

cell vector_new(**int** size, **cell** fill)

if $(size \equiv 0)$ return $Zero_Vector$; **return** vector_new_imp(size, btrue, fill);

if $(fill_p)$

return r;

}

38.

```
\S 31
                                                                                                          VECTORS
        LossLess Programming Environment
       \langle Externalised global variables 7\rangle + \equiv
  extern cell Zero_Vector;
     \langle \text{Protected Globals 21} \rangle + \equiv
32.
  \&Zero\_Vector,
33. \langle Global initialisation _3\rangle +\equiv
  Zero\_Vector = vector\_new\_imp(0, 0, 0);
34. \langle \text{Pre-initialise } Small\_Int \& \text{ other gc-sensitive buffers } 15 \rangle + \equiv
  Zero\_Vector = NIL;
      Separate storage means separate garbage collection and a different allocator. vector_new_imp, again,
is broadly similar to atom without the need for preallocated storage.
      \langle Function declarations \rangle + \equiv
  cell vector_new(int, cell);
  cell vector_new_imp(int, boolean, cell);
  cell vector_new_list(cell, int);
  cell vector_sub(cell, int, int, int, int, cell);
37.
      cell vector_new_imp(int size, boolean fill_p, cell fill)
     \mathbf{int}\ \mathit{wsize}\,,\ \mathit{off}\,,\ i;
     \mathbf{cell} \ r;
     wsize = vector\_realsize(size);
     if (Vectors\_Free + wsize \ge Vectors\_Poolsize) {
        gc\_vectors();
        while (Vectors\_Free + wsize \ge (Vectors\_Poolsize - (Vectors\_Poolsize/2))) new\_vector\_segment();
     r = atom(NIL, NIL, FORMAT_VECTOR);
     off = Vectors\_Free;
     Vectors\_Free += wsize;
                                                     /* must be first */
     vector\_offset(r) = off + VECTOR\_HEAD;
     vector\_length(r) = size;
     vector\_cell(r) = r;
```

39. *vector_new_list* turns a *list* of *pairs* into a *vector*.

```
 \begin{aligned} & \textbf{cell} \ \textit{vector\_new\_list}(\textbf{cell} \ \textit{list}, \textbf{int} \ \textit{len}) \\ \{ & \textbf{cell} \ r; \\ & \textbf{cell} \ r; \\ & \textbf{int} \ i; \\ & r = \textit{vector\_new}(\textit{len}, 0); \\ & \textbf{for} \ (i = 0; \ i < \textit{len}; \ i++) \ \{ \\ & \textit{vector\_ref}(r, i) = \textit{car}(\textit{list}); \\ & \textit{list} = \textit{cdr}(\textit{list}); \\ \} & \textbf{return} \ r; \\ \} \end{aligned}
```

40. Although a little early in the narrative $vector_sub$ is defined here because it's the only other function substantially dealing with vector data.

```
 \begin{array}{l} \textbf{cell} \ \textit{vector\_sub}(\textbf{cell} \ \textit{src}, \textbf{int} \ \textit{srcfrom}, \textbf{int} \ \textit{srcto}, \textbf{int} \ \textit{dstfrom}, \textbf{int} \ \textit{dstto}, \textbf{cell} \ \textit{fill}) \\ \{ & \textbf{cell} \ \textit{dst}; \\ \textbf{int} \ \textit{copy}, \ \textit{i}; \\ \textit{copy} = \textit{srcto} - \textit{srcfrom}; \\ \textbf{if} \ (\textit{dstto} < 0) \ \textit{dstto} = \textit{dstfrom} + \textit{copy}; \\ \textit{dst} = \textit{vector\_new\_imp}(\textit{dstto}, 0, 0); \\ \textbf{for} \ (\textit{i} = 0; \ \textit{i} < \textit{dstfrom}; \ \textit{i} + ) \ \textit{vector\_ref}(\textit{dst}, \textit{i}) = \textit{fill}; \\ \textbf{for} \ (\textit{i} = \textit{srcfrom}; \ \textit{i} < \textit{srcto}; \ \textit{i} + +) \\ \textit{vector\_ref} \ (\textit{dst}, (\textit{dstfrom} - \textit{srcfrom}) + \textit{i}) = \textit{vector\_ref} \ (\textit{src}, \textit{i}); \\ \textbf{for} \ (\textit{i} = \textit{dstfrom} + \textit{copy}; \ \textit{i} < \textit{dstto}; \ \textit{i} + +) \ \textit{vector\_ref} \ (\textit{dst}, \textit{i}) = \textit{fill}; \\ \textbf{return} \ \textit{dst}; \\ \} \end{array}
```

41. Garbage Collection. The garbage collector is a straightforward mark and sweep collector. *mark* is called for every entry in ROOTS to recursively set the mark bit on every reachable *pair*, then the whole pool is scanned and any *pairs* which aren't marked are added to the free list.

ROOTS is a Λ -terminated C array of objects to protect from collection. I can't think of any better way of declaring it but hard-coding it right here.

```
\mathbf{cell} * \mathtt{ROOTS}[] = \{ \langle \text{ Protected Globals 21} \rangle, \Lambda \};
```

42. ⟨Externalised global variables 7⟩ +≡ extern cell *ROOTS;

```
43. ⟨Function declarations 8⟩ +≡
int gc(void);
int gc_vectors(void);
void mark(cell);
int sweep(void);
```

§44

```
44.
      void mark(cell next)
    cell parent, prev;
    int i;
    parent = prev = NIL;
    while (1) {
       if (\neg(special\_p(next) \lor mark\_p(next))) {
         if (vector_p(next)) {
                                 /* S0 \rightarrow S.1 */
            mark\_set(next);
            vector\_cell(next) = next;
            if (vector\_length(next) > 0) {
              state\_set(next);
              vector\_index(next) = 0;
              prev = vector\_ref(next, 0);
              vector\_ref(next, 0) = parent;
              parent = next;
              next = prev;
         }
         else if (\neg acar_p(next) \land acdr_p(next)) {
                                                       /* S0 \rightarrow S2 */
            prev = cdr(next);
            cdr(next) = parent;
            parent = next;
            next = prev;
            mark_set(parent);

            state\_set(parent);
         else {
                    /* S0 \rightarrow S1 */
            mark\_set(next);
       }
       else {
         if (null\_p(parent)) break;
                                       /* S.1 \rightarrow S.1/done */
         if (vector_p(parent)) {
            i = vector\_index(parent);
            if ((i+1) < vector\_length(parent)) {
              prev = vector\_ref(parent, i + 1);
              vector\_ref(parent, i + 1) = vector\_ref(parent, i);
              vector\_ref(parent, i) = next;
              next = prev;
              vector\_index(parent) = i + 1;
            else {
                       /* S.1 \rightarrow done */
              state\_clear(parent);
              prev = parent;
```

GARBAGE COLLECTION

```
parent = vector\_ref(prev, i);
           vector\_ref(prev, i) = next;
           next = prev;
         }
      }
                                    /* S1 \rightarrow S2 */
      else if (state\_p(parent)) {
         prev = cdr(parent);
         cdr(parent) = car(parent);
         car(parent) = next;
         state_clear(parent);
         next = prev;
      else if (acdr_p(parent)) { /* S2 \rightarrow done */
         prev = parent;
         parent = cdr(prev);
         cdr(prev) = next;
         next = prev;
      else {
         error (ERR_UNIMPLEMENTED, NIL);
    }
  }
int sweep(void)
  int count, i;
  Cells\_Free = NIL;
  count = 0;
  if (\neg mark_p(i)) {
       tag(i) = TAG_NONE;
      cdr(i) = Cells\_Free;
       Cells\_Free = i;
      count ++;
    }
    else {
      mark\_clear(i);
  \mathbf{return}\ count;
\mathbf{int}\ gc(\mathbf{void})
  int sk, i;
  if (\neg null\_p(RTS)) {
    sk = vector\_length(RTS);
    vector\_length(RTS) = RTSp + 1;
  for (i = 0; ROOTS[i]; i++) mark(*ROOTS[i]);
  for (i = SCHAR\_MIN; i \leq SCHAR\_MAX; i++) mark(Small\_Int[(unsigned char) i]);
```

```
GARBAGE COLLECTION
```

```
 \begin{array}{ll} & \textbf{if} \ (\neg null\_p(\mathtt{RTS})) \ \ vector\_length(\mathtt{RTS}) = sk; \\ & \textbf{return} \ \ sweep(\ ); \\ & \\ \end{array} \}
```

45. *vector* garbage collection works by using the *pairs* garbage collector to scan ROOTS and determine which vectors are really in use then removes any which aren't from VECTORS, decrementing *Vectors_Free* if it can.

```
int gc\_vectors(\mathbf{void})
  \mathbf{int}\ to,\ from,\ d,\ i,\ r;
  (Unmark all vectors 46)
  from = to = 0:
  while (from < Vectors_Free) {
    d = vector\_realsize(VECTOR[from + VECTOR\_SIZE]);
    \mathbf{if} \ (\neg null\_p (\mathtt{VECTOR}[from + \mathtt{VECTOR\_CELL}])) \ \{
      if (to \neq from) {
         vector\_offset(VECTOR[to + VECTOR\_CELL]) = to + VECTOR\_HEAD;
       to += d;
    from += d;
  r = Vectors\_Free - to;
  Vectors\_Free = to;
  return r;
}
```

46. To "unmark" a vector, all the links in VECTOR back to the cell which refers to it $(vector_cell)$ are set to NIL. gc will re-set the link in any vectors that it can reach.

This code is used in section 45.

47. Objects. Although not objects per se, the first objects which will be defined are three stacks. We could define the run-time stack later because it's not used until the virtual machine is implemented but the implementations mirror each other and the internal VM stack is required before real objects can be defined. Also the run-time stack uses the VM stack in its implementation.

The compiler stack is included here because it's identical to the VM stack.

The VM stack is a pointer to the head of a *list*. This means that accessing the top few elements of the stack—especially pushing and popping a single object—is effectively free but accessing an arbitrary part of the stack requires an expensive walk over each item in turn.

On the other hand the run-time stack is stored in a *vector* with a pointer *RTSp* to the current head of the stack, which is -1 if the stack is empty.

This has the obvious disadvantage that its storage space is finite and occasionally the whole stack will need to be copied into a new, larger *vector* (and conversely it may waste space or require occasional trimming). On the other hand random access to any part of the stack has the same (negligable) cost.

When it's not ambiguous "stack" in this document refers to the run-time stack; the VM stack is an implementation detail. In fact the run-time stack is also an implementation detail but the VM stack is an implementation detail of that implementation detail; do you like recursion yet?.

The main interface to each stack is its push/pop/ref/clear functions. There are some additional handlers for the run-time stack.

```
#define ERR_UNDERFLOW "underflow"
#define ERR_OVERFLOW "overflow"
#define CHECK_UNDERFLOW(s) if (null_p(s)) error (ERR_UNDERFLOW, VOID)
\#define RTS_UNDERFLOW(p) if ((p) < -1) error (ERR_UNDERFLOW, RTS)
#define RTS_OVERFLOW(p) if ((p) > RTSp) error (ERR_OVERFLOW, RTS)
\langle \text{Global variables } 6 \rangle + \equiv
  cell CTS = NIL;
  cell RTS = NIL;
  cell VMS = NIL;
  int RTS\_Size = 0;
  int RTSp = -1;
    \langle \text{Externalised global variables } 7 \rangle + \equiv
  extern cell CTS, RTS, VMS:
  extern int RTS_Size, RTSp;
     \langle \text{Protected Globals 21} \rangle + \equiv
  &CTS, &RTS, &VMS,
50. \langle \text{Pre-initialise } Small\_Int \& \text{ other gc-sensitive buffers } 15 \rangle + \equiv
  CTS = RTS = VMS = NIL;
  RTS\_Size = 0;
  RTSp = -1;
```

```
\langle Function declarations \rangle + \equiv
  cell cts_pop(void);
  void cts_push(cell);
  cell cts_ref(void);
  void cts_set(cell);
  cell rts_pop(int);
  void rts_prepare(int);
  void rts_push(cell);
  cell rts_ref(int);
  cell rts_ref_abs(int);
  void rts_set(int, cell);
  void rts_set_abs(int, cell);
  cell vms\_pop(\mathbf{void});
  void vms_push(cell);
  cell vms_ref(void);
  void vms_set(cell);
     The VM and compiler stacks VMS and CTS are built on lists.
#define vms_clear() ((void) vms_pop())
  cell \ vms\_pop(void)
    \mathbf{cell} \ r;
    CHECK_UNDERFLOW(VMS);
    r = car(VMS);
    \mathtt{VMS} = cdr(\mathtt{VMS});
    return r;
  void vms_push(cell item)
  { VMS = cons(item, VMS); }
  cell vms_ref(void)
    CHECK_UNDERFLOW(VMS);
    return car(VMS);
  void vms_set(cell item)
    CHECK_UNDERFLOW(VMS);
    car(VMS) = item;
```

53. CTS is treated identically to VMS. Using the C preprocessor for this would be unnecessarily inelegant so instead here is a delicious bowl of pasta.

```
#define cts_clear() ((void) cts_pop())
#define cts_reset() CTS = NIL
  cell cts_pop()
    \mathbf{cell} \ r;
    CHECK_UNDERFLOW(CTS);
    r = car(CTS);
    CTS = cdr(CTS);
    return r;
  void cts_push(cell item)
  \{ CTS = cons(item, CTS); \}
  cell cts_ref(void)
    CHECK_UNDERFLOW(CTS);
    return car(CTS);
  void cts_set(cell item)
    CHECK_UNDERFLOW(CTS);
    car(CTS) = item;
  }
```

54. Being built on a vector the run-time stack needs to increase its size when it's full. Functions can call $rts_prepare$ to ensure that the stack is big enough for their needs.

```
#define RTS_SEGMENT #1000  
void rts\_prepare(int\ need) {
    int b,\ s;
    if (RTSp+need \geq RTS\_Size) {
        b= RTS_SEGMENT * ((need+ RTS_SEGMENT)/RTS_SEGMENT);
        s= RTS\_Size+b;
        RTS = vector\_sub(RTS, 0, RTS\_Size, 0, s, UNDEFINED);
        RTS\_Size=s;
    }
}
```

55. Otherwise, the run-time stack has the same interface but a different implementation.

```
#define rts\_clear(c) ((void) rts\_pop(c))
#define rts\_reset() Fp = RTSp = -1;
  cell rts_pop(int count)
    RTS_UNDERFLOW(RTSp - count);
    RTSp -= count;
    return vector\_ref(RTS, RTSp + 1);
  void rts_push(cell o)
    vms_push(o);
    rts\_prepare(1);
    vector\_ref(RTS, ++RTSp) = vms\_pop();
  cell rts_ref(int d)
    RTS_UNDERFLOW(RTSp - d);
    RTS_OVERFLOW(RTSp - d);
    return vector\_ref(RTS, RTSp - d);
  cell rts_ref_abs(int d)
    RTS_UNDERFLOW(d);
    RTS_OVERFLOW(d);
    return vector_ref (RTS, d);
  void rts\_set(\mathbf{int}\ d, \mathbf{cell}\ v)
    RTS_UNDERFLOW(RTSp - d);
    RTS_OVERFLOW(RTSp - d);
    vector\_ref(RTS, RTSp - d) = v;
  void rts\_set\_abs(\mathbf{int}\ d, \mathbf{cell}\ v)
    \mathtt{RTS\_UNDERFLOW}(d);
    RTS_OVERFLOW(d);
    vector\_ref(\mathtt{RTS},d) = v;
  }
```

56. Symbols. With the basics in place, the first thing to define is *symbols*; they're not needed yet but everything becomes easier with them extant and they depend on nothing but themselves since they are themselves.

symbols are never garbage collected. This was not a conscious decision it just doesn't seem like it matters. Instead, every symbol once created is immediately added to the Symbol_Table list. When a reference to a symbol is requested, the object in this list is returned.

Eventually this should implement a hash table but I'm not making one of those this morning.

Owing to the nasty c-to-perl-to-c route that I've taken, combined with plans for vector/byte storage, the storage backing symbols is going to be hairy without explanation (for now it's a mini duplicate of vector storage).

```
#define sym(s) symbol((s), 1)
#define symbol_length car
#define symbol_offset cdr
#define symbol\_store(s) (SYMBOL + symbol\_offset(s))
\langle \text{Global variables } 6 \rangle + \equiv
  cell Symbol_{-}Table = NIL;
  char *SYMBOL = \Lambda;
  int Symbol\_Free = 0;
  int Symbol\_Poolsize = 0;
      \langle Externalised global variables 7\rangle + \equiv
  extern cell Symbol_Table;
  extern char *SYMBOL;
  extern int Symbol_Free, Symbol_Poolsize;
      \langle \text{Protected Globals 21} \rangle + \equiv
  &Symbol\_Table,
     \langle Function declarations 8 \rangle + \equiv
  cell symbol(char *, boolean);
  void symbol\_expand(\mathbf{void});
  void symbol_reify(cell);
  boolean symbol_same_p(cell, cell);
  cell symbol_steal(char *);
      \langle \text{Pre-initialise } Small\_Int \& \text{ other gc-sensitive buffers } 15 \rangle + \equiv
  free(SYMBOL);
  SYMBOL = \Lambda;
  Symbol\_Poolsize = Symbol\_Free = 0;
  Symbol\_Table = NIL;
61.
      void symbol_expand(void)
     char *new;
     new = realloc(SYMBOL, Symbol_Poolsize + HEAP_SEGMENT);
     ERR_0OM_P(new);
     Symbol\_Poolsize += HEAP\_SEGMENT;
     SYMBOL = new;
  }
```

62. A *symbol* can "steal" storage from SYMBOL which results in an **object** which can be mostly treated like a normal *symbol*, used to compare a potentially new *symbol* with those currently stored in *Symbol_Table*. This is the closest that *symbols* get to being garbage collected.

```
\mathbf{cell} \ symbol\_steal(\mathbf{char} \ *cstr)
    \mathbf{cell} \ r;
    int len;
    len = strlen(cstr);
    while (Symbol\_Free + len > Symbol\_Poolsize) symbol\_expand();
    r = atom(len, Symbol\_Free, FORMAT\_SYMBOL);
    memcpy(SYMBOL + Symbol\_Free, cstr, len);
                                                    /* Symbol_Free is not incremented here */
    return r;
  }
63. Temporary symbols compare byte-by-byte with existing symbols. This is not efficient at all.
  boolean symbol_same_p(cell maybe, cell match)
    char *pmaybe, *pmatch;
    int i, len;
    len = symbol\_length(match);
    if (symbol\_length(maybe) \neq len) return bfalse;
    pmaybe = symbol\_store(maybe);
    pmatch = symbol\_store(match);
    if (maybe \equiv match)
                             /* This shouldn't happen */
       return btrue;
    for (i = 0; i < len; i++) {
       if (pmaybe[i] \neq pmatch[i]) return bfalse;
    return btrue;
64.
      void symbol_reify(cell s)
    Symbol\_Free += symbol\_length(s);
    Symbol\_Table = cons(s, Symbol\_Table);
65.
      cell symbol(char *cstr, boolean permanent_p)
  {
    cell st, s;
    s = symbol\_steal(cstr);
    st = Symbol\_Table;
    while (\neg null\_p(st)) {
      if (symbol\_same\_p(s, car(st))) return car(st);
       st = cdr(st);
    if (permanent_p) symbol_reify(s);
    return s;
```

23

Numbers. The only numbers supported by this early implementation of LossLess are signed integers that fit in a single **cell** (ie. 32-bit integers).

The 256 numbers closest to 0 (ie. from -#80 to +#7f) are preallocated during initialisation. If you live in a parallel universe where the char type isn't 8 bits then adjust those numbers accordingly.

```
#define fixint_p(p) (integer_p(p) \land null_p(int_next(p)))
\#define smallint_p(p) (fixint_p(p) \land int_value(p) \ge SCHAR_MIN \land int_value(p) \le SCHAR_MAX)
\#\mathbf{define} \quad int\_value(p) \quad ((\mathbf{int})(car(p)))
#define int_next cdr
\langle \text{Global variables } 6 \rangle + \equiv
  cell Small\_Int[UCHAR\_MAX + 1];
```

 $\langle \text{Externalised global variables } 7 \rangle + \equiv$ extern cell *Small_Int;

 \langle Function declarations $\rangle + \equiv$

Even though the Small_Int objects are about to be created, in order to create objects garbage collection will happen and assume that Small-Int has already been initialised and attempt to protect data which don't exist from collection. This is a silly solution but I'm leaving it alone until I have a better memory model.

```
\langle \text{Pre-initialise } Small\_Int \& \text{ other gc-sensitive buffers } 15 \rangle + \equiv
   for (i = 0; i < 256; i++) Small_Int[i] = NIL;
       \langle \text{Global initialisation } 3 \rangle + \equiv
   for (i = SCHAR\_MIN; i \leq SCHAR\_MAX; i++)
```

 $Small_Int[(\mathbf{unsigned\ char})\ i] = int_new_imp(i, NIL);$

As with vectors, int_new checks whether it should return an object from Small_Int or build a new one.

```
cell int_new_imp(int, cell);
  cell int\_new(\mathbf{int});
     cell int_new_imp(int value, cell next)
    if (\neg null\_p(next)) error (ERR_UNIMPLEMENTED, NIL);
    return atom((cell) value, next, FORMAT_INTEGER);
72.
      cell int\_new(\mathbf{int}\ value)
    if (value > SCHAR\_MIN \land value < SCHAR\_MAX)
       return Small_Int[(unsigned char) value];
    return int_new_imp(value, NIL);
```

73. Pairs & Lists. Of course *pairs*—and so by definition *lists*—have already been implemented but so far only enough to implement core features. Here we define handlers for operations specifically on *list* objects.

First to count it's length a *list* is simply walked from head to tail. It is not considered an error if the *list* is improper (or not a *list* at all). To indicate this case the returned length is negated.

```
⟨ Function declarations 8⟩ +≡
  int list_length(cell);
  predicate list_p(cell, predicate, cell *);
  cell list_reverse_m(cell, boolean);

74. int list_length(cell l)
  {
   int c = 0;
   if (null_p(l)) return 0;
   for (; pair_p(l); l = cdr(l)) c++;
   if (¬null_p(l)) c = -(c+1);
   return c;
  }
```

75. A *list* is either NIL or a pair with one restriction, that its *cdr* must itself be a *list*. The size of the *list* is also counted to avoid walking it twice but nothing uses that (yet?).

```
 \begin{array}{l} \textbf{predicate } \textit{list\_p}(\textbf{cell } o, \textbf{predicate } \textit{improper\_p}, \textbf{cell } *\textit{sum}) \\ \{ \\ \textbf{int } c = 0; \\ \textbf{if } (\textit{null\_p}(o)) \ \{ \\ \textbf{if } (\textit{sum} \neq \Lambda) \ *\textit{sum} = \textit{int\_new}(0); \\ \textbf{return } \texttt{TRUE}; \\ \} \\ \textbf{while } (\textit{pair\_p}(o)) \ \{ \\ o = \textit{cdr}(o); \\ c++; \\ \} \\ \textbf{if } (\textit{sum} \neq \Lambda) \ *\textit{sum} = \textit{int\_new}(c); \\ \textbf{if } (\textit{null\_p}(o)) \ \textbf{return } \texttt{TRUE}; \\ \textbf{if } (\textit{sum} \neq \Lambda) \ *\textit{sum} = \textit{int\_new}(-(c+1)); \\ \textbf{return } \textit{improper\_p}; \\ \} \end{array}
```

```
76. A proper list can be reversed simply into a new list.
```

```
#define ERR_IMPROPER_LIST "improper-list"
  cell list_reverse(cell l, cell *improper, cell *sum)
    cell saved, r;
    int c;
    saved = l;
    c = 0;
    vms_push(NIL);
    while (\neg null\_p(l)) {
       if (\neg pair_{-}p(l)) {
         r = vms\_pop();
         if (improper \neq \Lambda) {
           *improper = l;
           if (sum \neq \Lambda) *sum = c;
           return r;
         }
         else error (ERR_IMPROPER_LIST, saved);
       vms\_set(cons(car(l), vms\_ref()));
       l = cdr(l);
       c++;
    if (sum \neq \Lambda) *sum = int\_new(c);
    return vms_pop();
```

77. Reversing a list in-place means maintaining a link to the previous pair (or NIL) and replacing each pair's cdr. The new head pair is returned, or FALSE if the list turned out to be improper.

```
cell list_reverse_m(cell l, boolean error_p)
  cell m, t, saved;
  saved = l;
  m = NIL;
  while (\neg null\_p(l)) {
    if (\neg pair_{-}p(l)) {
                         /* TODO: repair? */
      if (\neg error_p)
         return FALSE;
      error (ERR_IMPROPER_LIST, saved);
    t = cdr(l);
    cdr(l) = m;
    m = l;
    l=t;
  return m;
}
```

78. Environments. In order to associate a value with a *symbol* (a variable) they are paired together in an *environment*.

Like an onion or an ogre¹, an *environment* has layers. The top layer is both the current layer and the current *environment*. The bottom layer is the root *environment Root*.

An environment is stored in an atom with the car pointing to the previous layer (or NIL in the root environment).

The *cdr* is a *list* of association *pairs* representing the variables in that layer. An association *pair* is a proper *list* with two items: an identifier, in this case a *symbol*, and a value.

environment-handling functions and macros are generally named "env".

```
#define ERR_BOUND "already-bound"
\#define ERR_UNBOUND "unbound"
#define env_empty() atom(NIL, NIL, FORMAT_ENVIRONMENT)
#define env_{-}extend(e) atom((e), NIL, FORMAT_ENVIRONMENT)
#define env_layer cdr
#define env_parent car
#define env_empty_p(e) (environment_p(e) \land null_p(car(e)) \land null_p(cdr(e)))
#define env\_root\_p(e) (environment\_p(e) \land null\_p(car(e)))
\langle \text{Global variables } 6 \rangle + \equiv
  cell Sym\_ERR\_BOUND = NIL;
  cell Sym_{-}ERR_{-}UNBOUND = NIL;
      \langle Externalised global variables 7\rangle + \equiv
  extern cell Sym_ERR_BOUND, Sym_ERR_UNBOUND;
      \langle \text{Global initialisation } 3 \rangle + \equiv
  Sym_{-}ERR_{-}BOUND = sym(ERR_{-}BOUND);
  Sym\_ERR\_UNBOUND = sym(ERR\_UNBOUND);
```

81. Searching through an *environment* starts at its top layer and walks along each *pair*. If it encounters a *pair* who's *symbol* matches, the value is returned. If not then the search repeats layer by layer until the *environment* is exhausted and UNDEFINED is returned.

env_search does not raise an error if a symbol isn't found. This means that UNDEFINED is the only value which cannot be stored in a variable as there is no way to distinguish its return from this function.

```
⟨ Function declarations 8⟩ +≡
  cell env_here(cell, cell);
  cell env_lift_stack(cell, cell);
  cell env_search(cell, cell);
  void env_set(cell, cell, boolean);

82. cell env_search(cell haystack, cell needle)
  {
    cell n;
    for (; ¬null_p(haystack); haystack = env_parent(haystack))
        for (n = env_layer(haystack); ¬null_p(n); n = cdr(n))
            if (caar(n) ≡ needle) return cadar(n);
        return UNDEFINED;
    }
```

¹ Or a cake.

```
83. cell env_here(cell haystack, cell needle)
{
   cell n;
   for (n = env_layer(haystack); ¬null_p(n); n = cdr(n))
      if (caar(n) ≡ needle) return cadar(n);
   return UNDEFINED;
}
```

84. To set a variable's value the *environment*'s top layer is first searched to see if the *symbol* is already bound. An **error** is raised if the symbol is bound (when running on behalf of *define!*) or not bound (when running on behalf of *set!*).

85. Updating an already-bound variable means removing the existing binding from the *environment* and inserting the new binding. During the walk over the layer t is one pair ahead of the pair being considered so that when name is found t's cdr can be changed, snipping the old binding out, so the first pair is checked specially.

```
 \langle \text{Mutate if bound } 85 \rangle \equiv \\ \text{if } (null\_p(env\_layer(e))) \ env\_set\_fail(\texttt{ERR\_UNBOUND}); \\ \text{if } (caar(env\_layer(e)) \equiv name) \ \{ \\ env\_layer(e) = cons(ass, cdr(env\_layer(e))); \\ vms\_clear(); \\ \text{return}; \\ \} \\ \text{for } (t = env\_layer(e); \neg null\_p(cdr(t)); \ t = cdr(t)) \ \{ \\ \text{if } (caadr(t) \equiv name) \ \{ \\ cdr(t) = cddr(t); \\ env\_layer(e) = cons(ass, env\_layer(e)); \\ vms\_clear(); \\ \text{return}; \\ \} \\ \} \\ env\_set\_fail(\texttt{ERR\_UNBOUND}); \\ \text{This code is used in section } 84.
```

LossLess Programming Environment

28

}

This code is used in section 84.

The case is simpler if the *name* must **not** be bound already as the new binding can be prepended to the layer after searching with no need for special cases.

```
\langle Mutate if unbound 86 \rangle \equiv
  if (\neg undefined\_p(env\_here(e, name))) env\_set\_fail(ERR\_BOUND);
  env\_layer(e) = cons(ass, env\_layer(e));
  vms\_clear();
  return;
```

87. Values are passed to functions on the stack. env_lift_stack moves these values from the stack into an

```
cell env_lift_stack(cell e, cell formals)
  cell ass, name, p, r;
  vms_push(p = NIL);
                          /* prepare a new layer */
  while (\neg null\_p(formals)) {
    if (pair_p(formals)) {
      name = car(formals);
      formals = cdr(formals);
    else {
      name = formals;
      formals = NIL;
    ass = rts\_pop(1);
    if (symbol_p(name)) {
      ass = cons(ass, NIL);
      ass = cons(name, ass);
      p = cons(ass, p);
      vms\_set(p);
          /* TODO: else assert(false_p(name)); */
r = env\_extend(e);
env\_layer(r) = p;
vms\_clear();
return r;
```

88. Closures & Compilers. Finally we have data structures to save run-time state: *closures*. The way the compiler and virtual machine work to get *closure* objects built is described below—here is only a description of their backing stores.

LossLess has two types of *closure*, *applicative* and *operative*. They store the same data in identical containers; the difference is in how they're used.

The data required to define a *closure* are a program & the *environment* to run it in. A *closure* in LossLess also contains the formals given in the **lambda** or **vov** expression that was used to define it.

Program code in LossLess is stored as compiled bytecode in a *vector* with an instruction pointer indicating the entry point (0 is not implied). The *closures* then look like this:

```
(APPLICATIVE \langle formals \rangle \langle environment \rangle \langle code \rangle \langle pointer \rangle)
(OPERATIVE \langle formals \rangle \langle environment \rangle \langle code \rangle \langle pointer \rangle)
```

However the *environment*, code and pointer are never referred to directly until the closure is unpicked by OP_APPLY_OP_APPLY_TAIL. Instead the objects effectively look like this:

```
(A|O \langle formals \rangle . \langle opaque\_closure \rangle)
#define applicative_closure cdr
#define applicative_formals car
\#define applicative\_new(f, e, p, i) closure\_new\_imp(FORMAT\_APPLICATIVE, (f), (e), (p), (i))
#define operative_closure cdr
#define operative_formals car
\#define operative\_new(f, e, p, i) closure\_new\_imp(FORMAT\_OPERATIVE, (f), (e), (p), (i))
\langle Function declarations \rangle + \equiv
  cell \ closure\_new\_imp(char, cell, cell, cell, cell);
      cell closure_new_imp(char ntag, cell formals, cell env, cell prog, cell ip)
89.
  {
     cell r;
     r = cons(int\_new(ip), NIL);
     r = cons(prog, r);
     r = cons(env, r);
     return atom(formals, r, ntag);
  }
```

90. Other than closures, and required in order to make them, the evaluator uses "compiler" objects that compile LossLess source code to VM bytecode. Each compiler is described in the structure primitive, containing the native function pointer to it.

```
#define compiler\_cname(c) COMPILER[car(c)].name #define compiler\_fn(c) COMPILER[car(c)].fn \langle Type definitions 5\rangle +\equiv typedef void (*native)(cell, cell, boolean); typedef struct { char *name; native fn; } primitive;
```

91. The contents of COMPILER are populated by the C compiler of this source. During initialisation Root then becomes the root environment filled with an association pair for each one.

```
 \begin{array}{l} \langle \, {\rm Global \,\, variables \,\, 6} \, \rangle \, + \equiv \\ \quad {\bf primitive \,\, COMPILER[\,]} \, = \, \, \{ \,\, \langle \, {\rm List \,\, of \,\, opcode \,\, primitives \,\, 517} \, \rangle, \,\, \{\Lambda,\Lambda\} \,\, \} \,\, ; \end{array}
```

92. ⟨Externalised global variables 7⟩ +≡
extern primitive *COMPILER;

93. Virtual Machine. This implementation of LossLess compiles user source code to an internal bytecode representation which is then executed sequentially by a virtual machine (VM).

Additionally to the myriad stacks already mentioned, the VM maintains (global!) state primarily in 6 registers. Two of these are simple flags (booleans) which indicate whether interpretation should continue.

- 1. Running is a flag raised (1) when the VM begins and lowered by user code to indicate that it should halt cleanly. This flag is checked on the beginning of each iteration of the VM's main loop.
- 2. Interrupt is normally lowered (0) and is raised in response to external events such as a unix signal. Long-running operations—especially those which could potentially run unbounded—check frequently for the state of this flag and abort and return immediately when it's raised.

The other four registers represent the computation.

- 3. Acc is the accumulator. Opcodes generally read and/or write this register to do their work. This is where the final result of computation will be found.
 - 4. Env holds the current environment. Changing this is the key to implementing closures.
- 5. Prog is the compiled bytecode of the currently running computation, a vector of VM opcodes with their in-line arguments.
- 6. Ip is the instruction pointer. This is an **int**, not a **cell** and must be boxed to be used outside of the VM.

Root and Prog_Main are also defined here which hold, respectively, the root environment and the virtual machine's starting program.

```
\langle \text{Global variables } 6 \rangle + \equiv
  boolean Interrupt = 0;
  boolean Running = 0;
  cell Acc = NIL;
  cell Env = NIL;
  cell Prog = NIL;
  cell Prog\_Main = NIL;
  cell Root = NIL;
  int Ip = 0;
     \langle \text{Externalised global variables } 7 \rangle + \equiv
  extern boolean Interrupt, Running;
  extern cell Acc, Env, Prog, Prog_Main, Root;
  extern int Ip;
     \langle \text{Protected Globals 21} \rangle + \equiv
  \&Acc, \&Env, \&Prog, \&Prog_Main, \&Root,
96. \langle \text{Pre-initialise } Small\_Int \& \text{ other gc-sensitive buffers } 15 \rangle + \equiv
  Acc = Env = Proq = Proq Main = Root = NIL;
  Interrupt = Running = Ip = 0;
```

97. The LossLess virtual machine is initialised by calling the code snippets built into the (Global initialisation 3) section then constructing the the root *environment* in *Root*.

Initialisation is divided into two phases. The first in vm_init sets up emergency jump points (which should never be reached) for errors which occur during initialisation or before the second phase.

The second phase establishes a jump buffer in *Goto_Begin* to support run-time errors that were not handled. It resets VM state which will not have had a chance to recover normally due to the computation aborting early.

The error handler's jump buffer *Goto_Error* on the other hand is established by *interpret* and does *not* reset any VM state, but does return to the previous jump buffer if the handler fails.

```
#define vm_init() do
            if (setjmp(Goto_Begin)) {
               Acc = sym("ABORT");
               return EXIT_FAILURE;
            if (setjmp(Goto_Error)) {
               Acc = sym("ABORT");
               return EXIT_FAILURE;
            vm_iinit_imp();
          while (0)
#define vm_prepare() do
            setjmp(Goto_Begin);
            vm\_prepare\_imp();
          while (0)
#define vm_runtime() do
            if (setjmp(Goto_Error)) {
                             /* TODO: call the handler */
               Ip = -1;
                \textbf{if} \ (\textit{Ip} < 0) \ \textit{longjmp}(\textit{Goto\_Begin}, 1); \\
          while (0)
\langle Function declarations \otimes \rangle + \equiv
  void vm_init_imp(\mathbf{void});
  void vm\_prepare\_imp(\mathbf{void});
  void vm\_reset(\mathbf{void});
```

```
98.
       void vm_init_imp(void)
  {
     \mathbf{cell}\ t;
     int i;
     primitive *n;
     \langle Pre-initialise Small_Int & other gc-sensitive buffers 15\rangle
     \langle Global initialisation _3\rangle
     Prog_{-}Main = compile_{-}main();
     i = 0;
     Root = atom(\mathtt{NIL},\mathtt{NIL},\mathtt{FORMAT\_ENVIRONMENT});
      \mathbf{for} \ (n = \mathtt{COMPILER} + i; \ n \neg fn \neq \Lambda; \ n = \mathtt{COMPILER} + (+\!\!+\!\!i)) \ \{
        t = atom(i, NIL, FORMAT\_COMPILER);
        t = cons(t, NIL);
        t = cons(sym(n \rightarrow name), t);
        env\_layer(Root) = cons(t, env\_layer(Root));
     Env = Root;
  }
99.
       void vm_prepare_imp(void)
     Acc = Prog = NIL;
     Env = Root;
     rts_reset();
  }
100. void vm_reset (void)
     Prog = Prog\_Main;
     Running = Interrupt = Ip = 0;
```

The VM enters a closure—aka. calls a function—by appending a frame header to the stack. A frame consists of any work-in-progress items on the stack followed by a fixed-size header. A frame's header captures the state of computation at the time it's created which is what lets another subroutine run and then return. The frame header contains 4 objects: $\ll Ip\ Prog\ Env\ Fp\gg$.

Fp is a quasi-register which points into the stack to the current frame's header. It's saved when entering a frame and its value set to that of the stack pointer RTSp. RTSp is restored to the saved value when returning from a frame.

```
#define FRAME_HEAD 4
#define frame_ip(f) rts_ref_abs((f) + 1)
\# \mathbf{define} \ \mathit{frame\_prog}(f) \ \mathit{rts\_ref\_abs}((f) + 2)
\#\mathbf{define} \ \mathit{frame\_env}(f) \ \mathit{rts\_ref\_abs}((f)+3)
#define frame\_fp(f) rts\_ref\_abs((f) + 4)
#define frame\_set\_ip(f, v) rts\_set\_abs((f) + 1, (v));
#define frame\_set\_prog(f, v) rts\_set\_abs((f) + 2, (v));
#define frame\_set\_env(f, v) rts\_set\_abs((f) + 3, (v));
#define frame\_set\_fp(f, v) rts\_set\_abs((f) + 4, (v));
\langle \text{Global variables } 6 \rangle + \equiv
  int Fp = -1;
102. \langle Externalised global variables 7 \rangle + \equiv
  extern int Fp;
103. \langle \text{Global initialisation } 3 \rangle + \equiv
  Fp = -1;
104. Creating a frame is pushing the header items onto the stack. Entering it is changing the VM's
registers that are now safe. This is done in two stages for some reason.
\langle Function declarations 8 \rangle + \equiv
  void frame_consume(void);
```

```
void frame_enter(cell, cell, cell);
  void frame_leave(void);
  void frame_push(int);
105. void frame_push(int ipdelta)
    rts\_push(int\_new(Ip + ipdelta));
    rts\_push(Prog);
    rts_push(Env);
    rts\_push(int\_new(Fp));
  }
106. void frame_enter(cell e, cell p, cell i)
    Env = e;
    Prog = p;
    Ip = i;
    Fp = RTSp - \mathtt{FRAME\_HEAD};
```

107. Leaving a frame means restoring the registers that were saved in it by $frame_push$ and then returning RTSp and Fp to their previous values; Fp from the header and RTSp as the current Fp minus the frame header in case there were previously any in-progress items on top of the stack.

```
void frame_leave(void)
{
   int prev;
   Ip = int_value(frame_ip(Fp));
   Prog = frame_prog(Fp);
   Env = frame_env(Fp);
   prev = int_value(frame_fp(Fp));
   rts_clear(FRAME_HEAD);
   Fp = prev;
}
```

108. Tail Recursion. TODO

36

This is a straight copy of what I wrote in perl which hasn't been used there. Looks about right. Might work.

```
\begin{tabular}{ll} \textbf{void} & frame\_consume(\textbf{void}) \\ \{ & \textbf{int} & src, & dst, & i; \\ & src & = Fp; \\ & dst & = int\_value(frame\_fp(src)); & /* & \textbf{Copy the parts of the old frame header that are needed} & */ \\ & frame\_set\_prog(src, frame\_prog(dst)); \\ & frame\_set\_ip(src, frame\_ip(dst)); & /* & \textbf{Move the active frame over the top of the previous one} & */ \\ & \textbf{for} & (i=1; & i \leq \texttt{FRAME\_HEAD}; & i++) \\ & & rts\_set\_abs(dst+i, rts\_ref\_abs(src+i)); \\ & rts\_clear(src-dst); \\ & Fp & -= src-dst; \\ \} \\ \end{tabular}
```

109. Interpreter. The workhorse of the virtual machine is interpret. After being reset with vm_reset , parsed (but not compiled) source code is put into Acc and the VM can be started by calling interpret.

```
\langle Function declarations \rangle + \equiv
  void interpret(void);
110.
#define ERR_INTERRUPTED "interrupted"
  void interpret(void)
    int ins;
    \mathbf{cell} \ tmp;
                   /* not saved in ROOTS */
    vm\_runtime();
    Running = 1;
    while (Running \land \neg Interrupt) {
       ins = int\_value(vector\_ref(Prog, Ip));
       switch (ins) {
         \langle Opcode implementations 10\rangle
#ifdef LL_TEST
         ⟨ Testing implementations 249⟩
#endif
       default: Interrupt = btrue;
```

if (Interrupt) error (ERR_INTERRUPTED, NIL);

111. I/O. Before embarking on the meat of the interpreter a final detour to describe routines to parse a string (or stream) of source code into s-expressions, and because it's useful to see what's being done routines to write them back again.

These routines use C's stdio for now to get a simple implementation finished.

112. Reader (or Parser). The s-expression reader is an ad-hoc LALR parser; a single byte is read to determine which type of form to parse. Bytes are then read one at a time to validate the syntax and create the appropriate object.

The reading routines call into themselves recursively (for which it cheats and relies on C's stack). To prevent it running out of control $Read_Level$ records the recursion depth and $read_form$ aborts if it exceeds READER_MAX_DEPTH.

The compiler's rather than the VM's stack is used for temporary storage so that error handling doesn't need to clean it up. This is safe provided the reader and compiler are never used simultaneously.

The parser often needs the byte that was used to determine which kind of form to parse (the one that was "looked ahead" at). Putback is a small buffer to contain this byte. In fact this buffer can hold two bytes to accommodate lisp's unquote-splicing operator $\langle \langle , \mathfrak{Q} \rangle \rangle$.

In order to perform tests of this primitive implementation the reader can be directed to "read" from a C-strings if $Read_Pointer$ is set to a value other than Λ .

```
#define ERR_RECURSION "recursion"
#define ERR_UNEXPECTED "unexpected"
#define WARN_AMBIGUOUS_SYMBOL "ambiguous"
#define READER_MAX_DEPTH 1024

       Putback[1] = '\0';
       return r;
    if (Read\_Pointer \neq \Lambda) {
       r = *Read\_Pointer;
       if (r \equiv '\0') r = EOF;
       Read\_Pointer ++;
       return r;
     return getchar();
  void unread_byte(\mathbf{char}\ c)
     Putback[1] = Putback[0];
     Putback[0] = c;
```

117. The internal test suite defined below needs to be able to evaluate code it supplies from hard-coded C-strings. The mechanism defined here to make this work is extremely brittle and not meant to be used by user code. Or for very long until it can be replaced by something less quonky.

```
 \begin{aligned} & \textbf{cell} \ \textit{read\_cstring}(\textbf{char} \ *src) \\ \{ & \textbf{cell} \ r; \\ & \textit{Read\_Pointer} = \textit{src}; \\ & r = \textit{read\_form}(\ ); \\ & \textit{Read\_Pointer} = \Lambda; \\ & \textbf{return} \ r; \end{aligned}
```

```
118. Even this primitive parser should support primitive comments.
```

```
int useful_byte(void)
  int c;
  while (\neg Interrupt) {
    c = read_byte();
    switch (c) {
    case '\'': case '\r': case '\t': continue;
    case '; ': c = read_byte();
      while (c \neq ' \n' \land \neg Interrupt) {
                                           /* read up to but not beyond the next newline */
        c = read\_byte();
        if (c \equiv EOF) return c;
      break;
                 /* go around again */
    default: return c;
                           /* includes EOF (which ≠ END_OF_FILE) */
  return EOF;
```

119. The public entry point to the reader is $read_sexp$. This simply resets the reader's global state and calls $read_form$.

```
cell read_sexp(void)
{
   cts_clear();
   Read_Level = 0;
   Putback[0] = Putback[1] = '\0';
   return read_form();
}
```

120. read_form reads a single (in most cases) byte which it uses to determine which parser function to dispatch to. The parser function will then return a complete s-expression (or raise an error).

121. Here are the different bytes which *read_form* can understand, starting with the non-byte value EOF which is an error if the reader is part-way through parsing an expression.

```
⟨ Reader forms 121⟩ ≡
case EOF:
  if (¬Read_Level) return END_OF_FILE;
  else error (ERR_ARITY_SYNTAX, NIL);
See also sections 123, 124, 125, 126, 127, and 128.
This code is used in section 120.
```

122. Lists and vectors are read in exactly the same way, differentiating by being told to expect the appropriate delimiter.

```
123. \langle \text{Reader forms } 121 \rangle + \equiv
case '(': return read_list(READ_CLOSE_PAREN);
case '[': return read_list(READ_CLOSE_BRACKET);
case ')': case ']':
     /* If Read_Level > 0 then read_form was called by read_list, otherwise read_sexp */
  if (¬Read_Level) error (ERR_ARITY_SYNTAX, NIL);
  else return c \equiv ')' ? READ_CLOSE_PAREN : READ_CLOSE_BRACKET;
124. A lone dot can only appear in a list and only before precisely one more expression. This is verified
later by read_list.
\langle \text{Reader forms } 121 \rangle + \equiv
case '.':
  if (¬Read_Level) error (ERR_ARITY_SYNTAX, NIL);
  c = useful_byte();
   \  \  \, \mathbf{if} \ (c \equiv \mathtt{EOF}) \ \mathbf{error} \ (\mathtt{ERR\_ARITY\_SYNTAX}, \mathtt{NIL}); \\
  unread_byte(c);
  return READ_DOT;
125. The only special form yet supported is booleans.
\langle \text{ Reader forms } 121 \rangle + \equiv
case '#': return read_special();
126. Strings and binary symbols aren't supported yet.
\langle\, {\rm Reader~forms}~ 121\, \rangle \, + \equiv
case '"': case '|': error (ERR_UNIMPLEMENTED, NIL);
```

127. In addition to the main syntactic characters, three other characters commonly have special meaning in lisps: $\langle \langle , \rangle \rangle$, $\langle \langle , \rangle \rangle$ and $\langle \langle , \rangle \rangle$. Can also appear as $\langle \langle , \mathfrak{o} \rangle \rangle$. Primarily these are for working with the macro expander.

In LossLess this syntax is unnecessary thanks to its first-class operatives but it's helpful so it's been retained. To differentiate between having parsed the syntactic form of these operators (eg. $\langle 'foo \rangle \rangle$ or $\langle '(bar\ baz)\rangle \rangle$) and their symbolic form (eg. $\langle (quote\ .\ foo)\rangle \rangle$ or $\langle (quote\ bar\ baz)\rangle \rangle$) an otherwise ordinary pair with the operative's symbol in the car is created with the tag FORMAT_SYNTAX. These syntax objects are treated specially by the compiler and the writer.

```
\langle \text{Reader forms } 121 \rangle + \equiv
case '\'': case '\'': n = useful\_byte();
  if (n \equiv EOF) error (ERR_ARITY_SYNTAX, NIL);
  unread_byte(n);
  if (n \equiv ')' \lor n \equiv ']') error (ERR_ARITY_SYNTAX, NIL);
  r = sym(c \equiv "","?" SYNTAX_QUASI : SYNTAX_QUOTE);
  return atom(r, read\_form(), FORMAT\_SYNTAX);
case ', ': c = read_byte();
  if (c \equiv EOF) error (ERR_ARITY_SYNTAX, NIL);
  if (c \equiv ')' \lor c \equiv ']') error (ERR_ARITY_SYNTAX, NIL);
  if (c \equiv 0)
     r = sym(SYNTAX_UNSPLICE);
     return atom(r, read\_form(), FORMAT\_SYNTAX);
  else {
     unread_byte(c);
    r = sym(SYNTAX_UNQUOTE);
     return atom(r, read\_form(), FORMAT\_SYNTAX);
        Anything else is a number or a symbol (and this byte is part of it) provided it's ASCII.
\langle \text{ Reader forms } 121 \rangle + \equiv
default:
  if (\neg isprint(c)) error (ERR_ARITY_SYNTAX, NIL);
  unread_byte(c);
   \textbf{if} \ (isdigit(c)) \ \textbf{return} \ read\_number(\ ); \\
  else return read_symbol();
```

129. $read_list$ sequentially reads complete forms until it encounters the closing delimiter $\langle \langle \rangle \rangle$ or $\langle \langle \rangle \rangle$. A pointer to the head of the list is saved and another pointer to its tail, write, is updated and used to insert the next object after it's been read, avoiding the need to reverse the list at the end.

```
cell read_list(cell delimiter)
  cell write, next, r;
  int count = 0;
  Read\_Level++;
  write = cons(NIL, NIL);
  cts\_push(write);
  while (1) {
    if (Interrupt) {
       cts\_pop();
       Read\_Level ---;
       return VOID;
    next = read\_form();
                                /* These must return or terminate unless n is a 'real' special */
    if (special_p(next)) {
       \langle Handle terminable 'forms' during list construction 130\rangle
    }
    count ++;
    cdr(write) = cons(NIL, NIL);
    write = cdr(write);
    car(write) = next;
  Read\_Level--;
  r = cdr(cts\_pop());
  if (delimiter \equiv READ\_CLOSE\_BRACKET)
    return vector\_new\_list(r, count);
  return count ? r : NIL;
```

130. read_form is expected to return an s-expression or raise an error if the input is invalid. In order to recognise when a closing parenthesis/bracket is read 3 'special' special forms are defined, READ_CLOSE_PAREN, READ_CLOSE_BRACKET and READ_DOT. Although these look and act like the other global constants they don't exist outside of the parser.

```
 \langle \text{ Handle terminable 'forms' during $list$ construction $130$} \rangle \equiv \\ \text{if } (eof\_p(next)) \text{ error } (\text{ERR\_ARITY\_SYNTAX,NIL}); \\ \text{else if } (next \equiv \text{READ\_CLOSE\_BRACKET} \lor next \equiv \text{READ\_CLOSE\_PAREN}) \; \{\\ \text{if } (next \neq delimiter) \text{ error } (\text{ERR\_ARITY\_SYNTAX,NIL}); \\ \text{break}; \\ \} \\ \text{else if } (next \equiv \text{READ\_DOT}) \; \{ \langle \text{Read dotted pair } 131 \rangle \}  This code is used in section 129.
```

131. Encountering a $\langle \langle . \rangle \rangle$ requires more special care than it deserves, made worse because if a *list* is dotted, a *syntax* object is created instead of a normal s-expression so that the style in which it's written out will be in the same that was read in.

This code is used in section 130.

132. If it's not a *list* or a *vector* (or a *string* ($\langle\langle " \rangle\rangle$), *specialform* ($\langle\langle \# \rangle\rangle$), *raw symbol* ($\langle\langle | \rangle\rangle$) or *comment*) then the form being read is an *atom*. If the atom starts with a numeric digit then control proceeds directly to *read_number* otherwise *read_symbol* reads enough to determine whether the atom is a number beginning with \pm or a valid or invalid symbol.

```
#define CHAR_TERMINATE "()[]\";_{\perp}\t\r\n"
#define terminable_p(c) strchr(CHAR\_TERMINATE, (c))
  cell read_number(void)
    char buf[12] = \{0\}; /* 2^{32} is 10 digits, also \pm and \Lambda */
    int c, i;
    long r;
    i = 0:
    while (1) {
       c = read\_byte();
                        /* TODO: If Read\_Level is 0 is this an error? */
       if (c \equiv EOF)
         error (ERR_ARITY_SYNTAX, NIL);
       if (i \equiv 0 \land (c \equiv , -, \lor c \equiv , +, )) buf [i++] = c;
       else if (isdigit(c)) buf [i++] = c;
       else if (\neg terminable_p(c)) error (ERR_ARITY_SYNTAX, NIL);
       else {
         unread\_byte(c);
         break;
       if (i > 11) error (ERR_UNIMPLEMENTED, NIL);
    r = atol(buf);
    if (r > INT\_MAX \lor r < INT\_MIN) error (ERR_UNIMPLEMENTED, NIL);
    return int\_new(r);
```

46

133. I could explain how booleans work here, or I could not.

```
 \begin{array}{l} \textbf{cell} \ \ read\_special(\textbf{void}) \\ \{ \\ \textbf{cell} \ \ r = \texttt{NIL}; \\ \textbf{int} \ \ c; \\ c = read\_byte(); \\ \textbf{if} \ \ (c \equiv \texttt{'f'}) \ \ r = \texttt{FALSE}; \\ \textbf{else if} \ \ \ (c \equiv \texttt{'t'}) \ \ r = \texttt{TRUE}; \\ \textbf{else error} \ \ (\texttt{ERR\_UNIMPLEMENTED,NIL}); \\ c = read\_byte(); \\ \textbf{if} \ \ (\neg terminable\_p(c)) \ \ \textbf{error} \ \ (\texttt{ERR\_ARITY\_SYNTAX,NIL}); \\ unread\_byte(c); \\ \textbf{return} \ \ r; \\ \} \end{array}
```

134. Although LossLess specifices (read: would specify) that there are no restrictions on the value of a *symbol*'s label, memory permitting, an artificial limit is being placed on the length of *symbols* of 16KB¹.

That said, there are no restrictions on the value of a *symbol*'s label, memory permitting. There are limits on what can be *parsed* as a *symbol* in source code. The limits on plain *symbol*s are primarily to avoid things that look vaguely like numbers to the human eye being parsed as *symbols* when the programmer thinks they should be parsed as a number. This helps to avoid mistakes like '3..14159' and harder to spot human errors being silently ignored.

- A symbol must not begin with a numeric digit or a syntactic character (comments $(\langle \langle ; \rangle \rangle)$), whitespace and everything recognised by read_form).
- The syntactic characters $\langle (\) \rangle$, $\langle (\) \rangle$ and $\langle (\) \rangle$ cannot appear anywhere in the *symbol*. nb. This means that the following otherwise syntactic characters *are* permitted in a symbol provided they do not occupy the first byte: $\langle (\ .) \rangle$, $\langle (\) \rangle$, and $\langle (\) \rangle$. You probably shouldn't do that lightly though.
- If the first character of a *symbol* is $\langle\!\langle \rangle\!\rangle$ or $\langle\!\langle + \rangle\!\rangle$ then it cannot be followed a numeric digit. $++\langle digit \rangle$ is valid.
- A $\langle\!\langle \rangle\!\rangle$ character or $\langle\!\langle + \rangle\!\rangle$ followed by a $\langle\!\langle . \rangle\!\rangle$ is a valid if strange *symbol* but a warning should probably be emitted by the parser if it finds that.

```
#define CHUNK_SIZE #80
#define READSYM_EOF_P if (c \equiv \text{EOF}) error (ERR_ARITY_SYNTAX, NIL)
       /* TODO: If Read_Level is 0 is this an error? */
  cell read_symbol(void)
     \mathbf{cell} \ r;
    \mathbf{char} \ *buf \ , \ *nbuf \ ;
     int c, i, s;
     c = read\_byte();
     READSYM_EOF_P;
     ERR_OOM_P(buf = malloc(CHUNK_SIZE));
     s = \texttt{CHUNK\_SIZE};
     (Read the first two bytes to check for a number 135)
     while (1) {\langle \text{Read bytes until an invalid or terminating character } 136 \rangle }
     buf[i] = '\0';
                         /* \Lambda-terminate the C-'string' */
     r = sym(buf);
     free(buf);
     return r;
  }
```

¹ 640KB was deemed to be far more than enough for anyone's needs.

Reading the first two bytes of a symbol is done specially to detect numbers beginning with ±. The first byte—which has already been read to check for EOF—is put into buf then if it matches \pm the next byte is also read and also put into buf.

If that second byte is a digit then we're actually reading a number so put the bytes that were read so far into Putback and go to read_number, which will read them again. If the second byte is $\langle \langle . \rangle \rangle$ then the symbol is valid but possibly a typo, so emit a warning and carry on.

```
\langle Read the first two bytes to check for a number 135\rangle \equiv
  buf[0] = c;
  i = 1;
  if (c \equiv '-' \lor c \equiv '+') {
     c = read\_byte();
    READSYM_EOF_P;
     buf[1] = c;
    i++;
                                /* This is a number! */
     if (isdigit(buf[1])) {
       unread\_byte(buf[1]);
       unread\_byte(buf[0]);
       free(buf);
       return read_number();
     else if (buf[1] \equiv ".") warn(WARN\_AMBIGUOUS\_SYMBOL, NIL);
     else if (\neg isprint(c)) error (ERR_ARITY_SYNTAX, NIL);
```

This code is used in section 134.

136. After the first two bytes we're definitely reading a symbol so anything goes except non-printable characters (which are an error) or syntactic terminators which indicate the end of the symbol.

```
\langle Read bytes until an invalid or terminating character 136\rangle \equiv
  c = read\_byte();
  READSYM_EOF_P;
  if (terminable_p(c)) {
     unread_byte(c);
     break;
  if (\neg isprint(c)) error (ERR_ARITY_SYNTAX, NIL);
  buf[i++] = c;
                    /* Enlarge buf if it's now full (this will also allow the \Lambda-terminator to fit) */
  if (i \equiv s) {
     nbuf = realloc(buf, s *= 2);
     if (nbuf \equiv \Lambda) {
       free(buf);
       error (ERR_OOM, NIL);
     buf = nbuf;
This code is used in section 134.
```

137. Writer. Although not an essential part of the language itself, the ability to display an s-expression to the user/programmer is obviously invaluable.

It is expected that this will (very!) shortly be changed to return a *string* representing the s-expression which can be passed on to an output routine but for the time being LossLess has no support for *strings* or output routines so the expression is written directly to *stdout*.

```
#define BUFFER_SEGMENT 1024
#define WRITER_MAX_DEPTH 1024
                                         /* gotta pick something */

140. Secret Objects. The hidden syntax object prints its syntactic form and then itself.

```
 \begin{split} \mathbf{ssize\_t} \  \, write\_syntax & (\mathbf{cell} \  \, sexp, \mathbf{char} \ *buf, \mathbf{ssize\_t} \  \, rem, \mathbf{int} \  \, depth) \\ \{ \\ \mathbf{ssize\_t} \  \, len = 0; \\ \mathbf{if} \  \, (\neg syntax\_p(sexp)) \  \, \mathbf{return} \  \, 0; \\ \mathbf{else} \  \, \mathbf{if} \  \, (car(sexp) \equiv sym(\mathtt{SYNTAX\_DOTTED})) \  \, append(buf, rem, ".", len); \\ \mathbf{else} \  \, \mathbf{if} \  \, (car(sexp) \equiv sym(\mathtt{SYNTAX\_QUOTE})) \  \, append(buf, rem, ".", len); \\ \mathbf{else} \  \, \mathbf{if} \  \, (car(sexp) \equiv sym(\mathtt{SYNTAX\_UNQUOTE})) \  \, append(buf, rem, ".", len); \\ \mathbf{else} \  \, \mathbf{if} \  \, (car(sexp) \equiv sym(\mathtt{SYNTAX\_UNQUOTE})) \  \, append(buf, rem, ".", len); \\ \mathbf{else} \  \, \mathbf{if} \  \, (car(sexp) \equiv sym(\mathtt{SYNTAX\_UNSPLICE})) \  \, append(buf, rem, ".", len); \\ \mathbf{append\_write}(buf, rem, cdr(sexp), depth + 1, len); \\ \mathbf{return} \  \, len; \\ \} \end{split}
```

ENVIRONMENT OBJECTS

141. Environment Objects. An environment prints its own layer and then the layers above it.

```
 \begin{split} \mathbf{ssize\_t} \ write\_environment(\mathbf{cell} \ sexp, \mathbf{char} \ *buf, \mathbf{ssize\_t} \ rem, \mathbf{int} \ depth) \\ \{ \\ \mathbf{ssize\_t} \ len = 0; \\ \mathbf{if} \ (\neg environment\_p(sexp)) \ \mathbf{return} \ 0; \\ append(buf, rem, "\#<environment\_", len); \\ append\_write(buf, rem, env\_layer(sexp), depth, len); \\ \mathbf{if} \ (\neg null\_p(env\_parent(sexp))) \ \{ \\ append(buf, rem, "\_ON_{\sqcup}", len); \\ append\_write(buf, rem, env\_parent(sexp), depth + 1, len); \\ append(buf, rem, ">", len); \\ \} \\ \mathbf{else} \ append(buf, rem, "\_ROOT>", len); \\ \mathbf{return} \ len; \\ \} \end{aligned}
```

LossLess Programming Environment

54

142. Exception Objects. These just need to look dangerous so they are in ALL CAPS.

```
ssize_t write_exception(cell sexp, char *buf, ssize_t rem, int depth)
  ssize_t len = 0;
  if (\neg exception\_p(sexp)) return 0;
  append(buf, rem, "\#<\texttt{EXCEPTION}_{\sqcup}", len);
  append_write(buf, rem, ex_id(sexp), depth, len);
  append\,(\mathit{buf}\,,\mathit{rem}\,,"_{\,\sqcup}",\mathit{len}\,);
  append\_write(buf, rem, ex\_detail(sexp), depth + 1, len);
  append(buf, rem, ">", len);
  return len;
```

143. Sequential Objects. The routines for a *list* and *vector* are more or less the same – write each item in turn with whitespace after each form but the last, with the appropriate delimiters. *lists* also need to deal with being improper.

```
ssize_t write_list(cell sexp, char *buf, ssize_t rem, int depth)
  ssize_t len = 0;
  if (\neg pair_p(sexp)) return 0;
  append(buf, rem, "(", len);
  while (pair_p(sexp)) {
     append\_write(buf, rem, car(sexp), depth + 1, len);
     if (pair_p(cdr(sexp)) \vee syntax_p(cdr(sexp))) append (buf, rem, "_{\sqcup}", len);
     else if (\neg null\_p(cdr(sexp)) \land \neg pair\_p(cdr(sexp)) \land \neg syntax\_p(cdr(sexp)))
       append(buf, rem, " \sqcup . \sqcup ", len);
     sexp = cdr(sexp);
  if (\neg null\_p(sexp)) append_write (buf, rem, sexp, depth + 1, len);
  append(buf, rem, ")", len);
  return len;
ssize_t write_vector(cell sexp, char *buf, ssize_t rem, int depth)
  int i;
  ssize_t len = 0;
  if (\neg vector\_p(sexp)) return 0;
  append(buf, rem, "[", len);
  for (i = 0; i < vector\_length(sexp); i++) {
     append\_write(buf, rem, vector\_ref(sexp, i), depth + 1, len);
     if (i + 1 < vector\_length(sexp)) append(buf, rem, "_{\sqcup}", len);
  append(buf, rem, "]", len);
  return len;
```

56

144. For the time being *write_bytecode* is only called (directly) by the unit tests; there is no object that represents bytecode for *write_form* to detect.

```
ssize_t write_bytecode(cell sexp, char *buf, ssize_t rem, int depth)
  int arg, ins, op;
  ssize_t len = 1;
  if (rem \leq 0) return -1;
  *buf +++ = '{\{}';
  rem --;
  op = 0;
  while (op < vector\_length(sexp)) {
     if (op) append(buf, rem, "$\_{\super}", len);
     ins = int\_value(vector\_ref(sexp, op));
     if (ins \ge OPCODE\_MAX) error (ERR_UNEXPECTED, NIL);
     append(buf, rem, OP[ins].name, len);
     \mathbf{for}\ (\mathit{arg} = 1;\ \mathit{arg} \leq \mathtt{OP}[\mathit{ins}].\mathit{nargs};\ \mathit{arg} +\!\!\!+\!\!\!+)\ \{
        append(buf, rem, "$\sqcup$", len);
        append\_write(buf, rem, vector\_ref(sexp, op + arg), depth + 1, len);
     op += 1 + OP[ins].nargs;
  }
  append(buf, rem, "}", len);
  return len;
```

145. write_form simply calls each writer in turn, stopping after the first one returning a positive number of bytes written or a negative number indicating that the buffer is full.

```
ssize_t write_form(cell sexp, char *buf, ssize_t rem, int depth)
  ssize_t len = 0;
  if (Interrupt) {
    if (\neg depth) append (buf, rem, "... \sqcup ", len);
    return len;
  if (depth > WRITER_MAX_DEPTH) error (ERR_RECURSION, NIL);
  if (undefined_p(sexp)) append(buf, rem, "#><", len);
                                                            /* nothing should ever print this */
  else if (eof_p(sexp)) append (buf, rem, "\# < eof > ", len);

                                                           /* NOP */;
  else if ((len = write\_vector(sexp, buf, rem, depth)))
  else append(buf, rem, "#<wtf?>", len);
                                              /* impossibru! */
  return len;
}
```

149. ⟨Externalised global variables 7⟩ +≡ extern opcode OP[OPCODE_MAX];

146. Opcodes. With the core infrastructure out of the way we can finally turn our attention to the virtual machine implementation, or the implementation of the opcodes that the compiler will turn LossLess code into.

The opcodes that the virtual machine can perform must be declared before anything can be said about them. They take the form of an **enum**, this one unnamed. This list is sorted alphabetically for want of anything else.

Also defined here are fetch and skip which opcode implementations will use to obtain their argument(s) from Prog or advance Ip, respectively.

```
#define skip(d) Ip += (d)
\# \mathbf{define} \ \mathit{fetch}(d) \ \mathit{vector\_ref}\left(\mathit{Prog}, \mathit{Ip} + (d)\right)
\langle \text{ Complex definitions \& macros } 146 \rangle \equiv

151. Basic Flow Control. The most basic opcodes that the virtual machine needs are those which control whether to operate and where.

```
152. \langle \text{Opcode implementations } 10 \rangle + \equiv
case OP_HALT:
  Running = 0;
  break;
case OP_JUMP:
  Ip = int\_value(fetch(1));
  break;
case OP_JUMP_FALSE:
  if (void_p(Acc)) error (ERR_UNEXPECTED, VOID);
  else if (false\_p(Acc)) Ip = int\_value(fetch(1));
  else skip(2);
  break;
case OP_JUMP_TRUE:
  if (void_p(Acc)) error (ERR_UNEXPECTED, VOID);
  else if (true\_p(Acc)) Ip = int\_value(fetch(1));
  else skip(2);
  break;
case OP_NOOP:
  skip(1);
  break;
153. OP_QUOTE isn't really flow control but I don't know where else to put it.
\langle \text{Opcode implementations } 10 \rangle + \equiv
case OP_QUOTE:
  Acc = fetch(1);
  skip(2);
  break;
```

```
154. Pairs & Lists. OP_CAR, OP_CDR, OP_NULL_P and OP_PAIR_P are self explanatory.
\langle \text{Opcode implementations } 10 \rangle + \equiv
case OP_CAR:
  Acc = car(Acc);
  skip(1);
  break;
case OP_CDR:
  Acc = cdr(Acc);
  skip(1);
  break;
case OP_NULL_P:
  Acc = null_p(Acc) ? TRUE : FALSE;
  skip(1);
  break;
case OP_PAIR_P:
  Acc = pair_p(Acc) ? TRUE : FALSE;
  skip(1);
  break;
155. OP_CONS consumes one stack item (for the cdr) and puts the new pair in Acc. OP_SNOC does the
opposite, pushing Acc's cdr to the stack and leaving its car in Acc.
\langle \text{Opcode implementations } 10 \rangle + \equiv
case OP_CONS:
  Acc = cons(Acc, rts\_pop(1));
  skip(1);
  break;
case OP_SNOC:
  rts\_push(cdr(Acc));
  Acc = car(Acc);
  skip(1);
  break;
156. Cons cell mutators clear take an item from the stack and clear Acc.
\langle \text{Opcode implementations } 10 \rangle + \equiv
case OP_SET_CAR_M:
  car(rts\_pop(1)) = Acc;
  Acc = VOID;
  skip(1);
  break;
case OP_SET_CDR_M:
  cdr(rts\_pop(1)) = Acc;
  Acc = VOID;
  skip(1);
  break;
```

break;

```
157. Other Objects. There is not much to say about these.
\langle \text{Opcode implementations } 10 \rangle + \equiv
case OP_LIST_P:
  if (¬false_p(fetch(2))) error (ERR_UNIMPLEMENTED, NIL);
  Acc = list_p(Acc, fetch(1), \Lambda);
  skip(3);
  break;
case OP_LIST_REVERSE:
  \textbf{if} \ (\neg \textit{true\_p}(fetch(1)) \lor \neg \textit{false\_p}(fetch(2))) \ \textbf{error} \ (\texttt{ERR\_UNIMPLEMENTED}, \texttt{NIL});\\
  Acc = list\_reverse(Acc, \Lambda, \Lambda);
  skip(3);
  break;
case OP_LIST_REVERSE_M:
  Acc = list\_reverse\_m(Acc, btrue);
  skip(1);
  break;
case OP_SYNTAX:
  Acc = atom(fetch(1), Acc, FORMAT_SYNTAX);
  skip(2);
```

```
§158
        LossLess Programming Environment
                                                                                                 STACK
158. Stack. OP_PUSH and OP_POP push the object in Acc onto the stack, or remove the top stack
object into Acc, respectively. OP_PEEK is OP_POP without removing the item from the stack.
  \mathtt{OP\_SWAP} swaps the object in Acc with the object on top of the stack.
  {\tt OP\_CYCLE} swaps the top two stack items with each other.
  OP_NIL pushes a NIL straight onto the stack without the need to quote it first.
\langle \text{Opcode implementations } 10 \rangle + \equiv
case OP_CYCLE:
  tmp = rts\_ref(0);
  rts\_set(0, rts\_ref(1));
  rts\_set(1, tmp);
  skip(1);
  break;
case OP_PEEK:
  Acc = rts\_ref(0);
  skip(1);
  break;
case OP_POP:
  Acc = rts\_pop(1);
  skip(1);
  break;
```

case OP_PUSH: $rts_push(Acc);$ skip(1);break; case OP_SWAP: tmp = Acc; $Acc = rts_ref(0);$ $rts_set(0, tmp);$ skip(1);break; case OP_NIL: $rts_push(NIL);$ skip(1);break;

break;

159. Environments. Get or mutate environment objects. OP_ENV_SET_ROOT_M isn't used yet. $\langle \text{Opcode implementations } 10 \rangle + \equiv$ case OP_ENVIRONMENT_P: $Acc = environment_p(Acc)$? TRUE : FALSE; skip(1);break; case OP_ENV_MUTATE_M: $env_set(rts_pop(1), fetch(1), Acc, true_p(fetch(2)));$ Acc = VOID;skip(3);break; case OP_ENV_QUOTE: Acc = Env;skip(1);break; case OP_ENV_ROOT: Acc = Root;skip(1);break; case OP_ENV_SET_ROOT_M: Root = Acc;/* *Root* is 'lost'! */ skip(1);break; To look up the value of a variable in an *environment* we use OP_LOOKUP which calls the (recursive) env_search, interpreting the UNDEFINED it might return. $\langle \text{Opcode implementations } 10 \rangle + \equiv$ case OP_LOOKUP: $vms_{-}push(Acc);$ $Acc = env_search(Env, vms_ref());$ **if** $(undefined_p(Acc))$ { $Acc = vms_pop();$ **error** (ERR_UNBOUND, Acc); $vms_pop();$ skip(1);

161. Closures. A closure is the combination of code to interpret and an environment to interpret it in. Usually a closure has arguments—making it useful—although in some cases a closure may work with global state or be idempotent.

In order to apply the arguments (if any) to the *closure* it must be entered by one of the opcodes OP_APPLY or OP_APPLY_TAIL. OP_APPLY_TAIL works identically to OP_APPLY and then consumes the stack frame which was created, allowing for *proper tail recursion* with further support from the compiler.

```
 \begin{split} &\langle \operatorname{Opcode\ implementations\ 10} \rangle +\equiv \\ &\mathbf{case\ 0P\_APPLY:} \\ &\mathbf{case\ 0P\_APPLY\_TAIL:} \\ &\mathit{tmp} = fetch(1); \\ &\mathit{vms\_push}(env\_lift\_stack(cadr(tmp), car(tmp))); \\ &\mathit{frame\_push}(2); \\ &\mathit{frame\_enter}(vms\_pop(), caddr(tmp), int\_value(cadddr(tmp))); \\ &\mathbf{if\ } (ins \equiv \mathtt{OP\_APPLY\_TAIL}) \ \mathit{frame\_consume}(); \\ &\mathbf{break}; \\ &\mathbf{case\ 0P\_RETURN:} \\ &\mathit{frame\_leave}(); \\ &\mathbf{break}; \end{split}
```

162. Creating a closure in the first place follows an identical procedure whether it's an applicative or an operative but creates a different type of object in each case.

```
\label{eq:case_op_lambda} $$\langle \operatorname{Opcode\ implementations\ 10} \rangle + \equiv \\ \operatorname{case\ OP\_LAMBDA}: \quad /* \ \operatorname{The\ applicative\ */} \\ Acc = applicative\_new(rts\_pop(1), Env, Prog, int\_value(fetch(1))); \\ skip(2); \\ \operatorname{break}; \\ \operatorname{case\ OP\_VOV:} \quad /* \ \operatorname{The\ operative\ */} \\ Acc = operative\_new(rts\_pop(1), Env, Prog, int\_value(fetch(1))); \\ skip(2); \\ \operatorname{break}; \\ $$
```

163. Compiler. The compiler needs to instruct the interpreter to compile more code and then run it, so these opcodes do that. OP_COMPILE compiles an s-expression into LossLess bytecode.

```
164. \langle Opcode implementations 10 \rangle +\equiv case OP_COMPILE: Acc = compile(Acc); skip(1); break;
```

165. OP_RUN interprets the bytecode in *Acc* in the current *environment*; the VM's live state is saved into a new stack *frame* then that *frame* is entered by executing the bytecode in *Acc*, starting at instruction 0.

```
\langle Opcode implementations 10 \rangle +\equiv case OP_RUN: frame_push(1); frame_enter(Env, Acc, 0); break;
```

166. OP_RUN_THERE is like OP_RUN except that the *environment* to interpret the bytecode in is taken from the stack rather than staying in the active *environment*.

```
 \begin{split} &\langle \, \text{Opcode implementations} \,\, \mathbf{10} \, \rangle \, + \equiv \\ &\mathbf{case} \,\, \mathbf{0P\_RUN\_THERE:} \\ & \, vms\_push(rts\_pop(1)); \\ & \, frame\_push(1); \\ & \, frame\_enter(vms\_pop(), Acc, 0); \\ & \, \mathbf{break:} \end{split}
```

167. Compiler. Speaking of the compiler, we can now turn our attention to writing it. The compiler is not advanced in any way but it is a little unusual. Due to the nature of first-class operatives, how to compile any expression can't be known until the combinator has been evaluated (read: compiled and then interpreted) in order to distinguish an applicative from an operative so that it knows whether to evaluate the arguments in the expression. I don't know if this qualifies it for a *Just-In-Time* compiler; I think *Finally-Able-To* is more suitable.

The compiler uses a small set of C macros which grow and fill *Compilation*—a *vector* holding the compilation in-progress.

```
#define ERR_COMPILE_DIRTY "compiler"

#define ERR_UNCOMBINABLE "uncombinable"

#define COMPILATION_SEGMENT #80

#define emitop(o) emit(int\_new(o))

#define emitq(o) do { emitop(OP\_QUOTE); emit(o); }

while (0) /* C... */

#define patch(i,v) (vector\_ref(Compilation,(i)) = (v))

#define undot(p) ((syntax\_p(p) \land car(p) \equiv Sym\_SYNTAX\_DOTTED)? cdr(p) : (p))

$\left(Compilation = NIL)$;

168. $\left(Externalised global variables 7\right) +\equiv extern int Here; extern cell Compilation;
```

```
169.
       \langle Function declarations \rangle + \equiv
  cell arity(cell, cell, int, boolean);
  cell arity_next(cell, cell, cell, boolean, boolean);
  int \ come from (void);
  cell compile(cell);
  cell compile_main(void);
  void compile_car(cell, cell, boolean);
  void compile_cdr(cell, cell, boolean);

  void compile_cons(cell, cell, boolean);
  void compile_define_m(cell, cell, boolean);
  void compile_env_current(cell, cell, boolean);
  void compile_env_root(cell, cell, boolean);
  void compile_error(cell, cell, boolean);
  void compile_eval(cell, cell, boolean);
  void compile_expression(cell, boolean);
  void compile_lambda(cell, cell, boolean);
  void compile_list(cell, cell, boolean);
  void compile_null_p(cell, cell, boolean);
  void compile_pair_p(cell, cell, boolean);
  void compile_quasicompiler(cell, cell, cell, int, boolean);
  void compile_quasiquote(cell, cell, boolean);
  void compile_quote(cell, cell, boolean);
  void compile_set_car_m(cell, cell, boolean);
  void compile_set_cdr_m(cell, cell, boolean);
  void compile_set_m(cell, cell, boolean);
  void compile_symbol_p(cell, cell, boolean);
  void compile_vov(cell, cell, boolean);
  void emit(cell);
     \langle \text{Protected Globals 21} \rangle + \equiv
  & Compilation,
       \langle \text{Pre-initialise } Small\_Int \& \text{ other gc-sensitive buffers } 15 \rangle + \equiv
  Compilation = NIL;
172. void emit(cell bc)
  {
    int l;
    l = vector\_length(Compilation);
    if (Here \geq l)
       Compilation = vector\_sub(Compilation, 0, l,
           0, l + \texttt{COMPILATION\_SEGMENT},
           OP_HALT);
    vector\_ref(Compilation, Here ++) = bc;
```

173. While compiling it frequently occurs that the value to emit isn't known at the time it's being emitted. The most common and obvious example of this is a forward jump who's address must immediately follow the opcode but the address won't be known until more compilation has been performed.

To make this work *comefrom* emits a NIL as a placeholder and returns its offset, which can later be passed in the first argument of *patch* to replace the NIL with the desired address etc.

```
int comefrom(void)
{
    emit(NIL);
    return Here - 1;
}
```

174. Compilation begins by preparing *Compilation* and CTS then recursively walks the tree in *source* dispatching to individual compilation routines to emit the appropriate bytecode.

```
 \begin{aligned} & \textbf{cell} \ compile(\textbf{cell} \ source) \\ & \{ \\ & \textbf{cell} \ r; \\ & Compilation = vector\_new(\texttt{COMPILATION\_SEGMENT}, int\_new(\texttt{OP\_HALT})); \\ & Here = 0; \\ & cts\_reset(); \\ & compile\_expression(source, 1); \\ & emitop(\texttt{OP\_RETURN}); \\ & r = vector\_sub(Compilation, 0, Here, 0, Here, \texttt{VOID}); \\ & Compilation = Zero\_Vector; \\ & \textbf{if} \ (\neg null\_p(\texttt{CTS})) \ \textbf{error} \ (\texttt{ERR\_COMPILE\_DIRTY}, source); \\ & \textbf{return} \ r; \end{aligned}
```

175. compile_main is used during initialisation to build the bytecode \ll OP_COMPILE OP_RUN OP_HALT \gg which is the program installed initially into the virtual machine.

```
\label{eq:compile_main} \begin{split} & \mathbf{cell} \ \ compile\_main(\mathbf{void}) \\ \{ & \mathbf{cell} \ \ r; \\ & r = vector\_new\_imp(3,0,0); \\ & vector\_ref(r,0) = int\_new(\mathtt{OP\_COMPILE}); \\ & vector\_ref(r,1) = int\_new(\mathtt{OP\_RUN}); \\ & vector\_ref(r,2) = int\_new(\mathtt{OP\_HALT}); \\ & \mathbf{return} \ \ r; \\ \} \end{split}
```

176. The first job of the compiler is to figure out what type of expression it's compiling, chiefly whether it's a *list* to combine or an *atom* which is itself.

```
void compile_expression(cell sexp, int tail_p)
{
   if (¬pair_p(sexp) ∧ ¬syntax_p(sexp)) {⟨ Compile an atom 177⟩}
   else {⟨ Compile a combiner 178⟩}
}
```

177. The only *atom* which doesn't evaluate to itself is a *symbol*. A *symbol* being evaluated references a variable which must be looked up in the active environment.

```
 \begin{split} &\langle \text{Compile an atom } 177 \rangle \equiv \\ & \text{if } (symbol\_p(sexp)) \; \{ \\ & emitq(sexp); \\ & emitop(\text{OP\_LOOKUP}); \\ & \} \\ & \text{else } \{ emitq(sexp); \} \end{split}
```

178. Combining a *list* requires more work. This is also where operatives obtain the property of being first-class objects by delaying compilation of all but the first expression in the *list* until after that compiled bytecode has been interpreted.

```
 \begin{array}{l} \langle \operatorname{Compile \ a \ combiner \ 178} \rangle \equiv \\ \operatorname{cell \ } args, \ \operatorname{combiner}; \\ \operatorname{combiner \ } = \operatorname{car}(\operatorname{sexp}); \\ \operatorname{args \ } = \operatorname{undot}(\operatorname{cdr}(\operatorname{sexp})); \\ \langle \operatorname{Search \ } Root \ \operatorname{for \ syntactic \ combiners \ 179} \rangle \\ \operatorname{if \ } (\operatorname{compiler \ } p(\operatorname{combiner})) \ \left\{ \langle \operatorname{Compile \ native \ combiner \ 180} \rangle \right\} \\ \operatorname{else \ } \operatorname{if \ } (\operatorname{applicative \ } p(\operatorname{combiner})) \ \left\{ \langle \operatorname{Compile \ applicative \ combiner \ 191} \rangle \right\} \\ \operatorname{else \ } \operatorname{if \ } (\operatorname{applicative \ } p(\operatorname{combiner})) \ \left\{ \langle \operatorname{Compile \ operative \ combiner \ 200} \rangle \right\} \\ \operatorname{else \ } \operatorname{if \ } (\operatorname{symbol \ } p(\operatorname{combiner}) \vee \operatorname{pair \ } p(\operatorname{combiner})) \ \left\{ \langle \operatorname{Compile \ unknown \ combiner \ 181} \rangle \right\} \\ \operatorname{else \ } \left\{ \operatorname{error \ } (\operatorname{ERR \ } \operatorname{UNCOMBINABLE}, \operatorname{combiner}); \ \right\} \\ \operatorname{This \ code \ is \ used \ in \ section \ 176}. \end{array}
```

179. If the combiner (sexp's car) is a syntax object then it represents the result of parsing (for example) $\langle (cexpression) \rangle$ into $\langle (cexpression) \rangle$ and it must always mean the $real\ quote$ operator, so syntax combiners are always looked for directly (and only) in Root.

```
 \langle \text{Search } \textit{Root } \text{ for syntactic combiners } 179 \rangle \equiv \\ \text{if } (\textit{syntax\_p}(\textit{sexp})) \ \{ \\ \text{cell } c; \\ c = \textit{env\_search}(\textit{Root}, \textit{combiner}); \\ \text{if } (\textit{undefined\_p}(c)) \ \text{error } (\texttt{ERR\_UNBOUND}, \textit{combiner}); \\ \textit{combiner} = c; \\ \}  This code is used in section 178.
```

180. A native compiler is simple; look up its address in COMPILER and go there. The individual native compilers are defined below.

```
\langle Compile native combiner 180\rangle \equiv compiler_fn(combiner)(combiner, args, tail_p); This code is used in section 178.
```

71

181. If the compiler doesn't know whether combiner is applicative or operative then that must be determined before args can be considered.

```
\langle Compile unknown combiner 181 \rangle \equiv
  emitq(args);
                         /\ast\, save args onto the stack \,\ast/\,
  emitop(OP_PUSH);
  compile\_expression(combiner, 0);
                                       /* evaluate the combiner, leaving it in Acc */
                         /* rebuild sexp with the evaluated combiner */
  emitop(OP\_CONS);
  emitop(	exttt{OP_COMPILE}); /* continue compiling } sexp */
                       /* run that code in the same environment */
  emitop(OP_RUN);
This code is used in section 178.
```

182. Function Bodies. Nearly everything has arguments to process and it's nearly always done in the same way. *arity* and *arity_next* work in concert to help the compiler implementations check how many arguments there are (but not their value or type) and raise any errors encountered.

arity pushes the minimum required arguments onto the compiler stack (in reverse) and returns a pointer to the rest of the argument list.

```
#define ERR_ARITY_EXTRA "extra"
\#define ERR_ARITY_MISSING "missing"
#define ERR_ARITY_SYNTAX "syntax"
#define arity\_error(e, c, a) error ((e), cons((c), (a)))
\langle \text{Global variables } 6 \rangle + \equiv
  cell Sym\_ERR\_ARITY\_EXTRA = NIL;
  cell Sym_ERR_ARITY_MISSING = NIL;
  cell Sym\_ERR\_ARITY\_SYNTAX = NIL;
       \langle Externalised global variables 7\rangle + \equiv
  extern cell Sym\_ERR\_ARITY\_EXTRA, Sym\_ERR\_ARITY\_MISSING, Sym\_ERR\_ARITY\_SYNTAX;
184. \langle Global initialisation 3\rangle + \equiv
  Sym\_ERR\_ARITY\_EXTRA = sym(ERR\_ARITY\_EXTRA);
  Sym\_ERR\_ARITY\_MISSING = sym(ERR\_ARITY\_MISSING);
  Sym\_ERR\_ARITY\_SYNTAX = sym(ERR\_ARITY\_SYNTAX);
185. cell arity(cell op, cell args, int min, boolean more_p)
    cell a = args;
    int i = 0;
    for ( ; i < min; i ++)  {
      if (null_p(a)) {
         if (compiler\_p(op) \lor operative\_p(op)) arity\_error(ERR\_ARITY\_SYNTAX, op, args);
         else arity_error(ERR_ARITY_MISSING, op, args);
      if (\neg pair_p(a)) arity_error(ERR_ARITY_SYNTAX, op, args);
      cts\_push(car(a));
      a = cdr(a);
    if (min \land \neg more\_p \land \neg null\_p(a)) {
      if (pair_p(a)) arity_error(ERR_ARITY_EXTRA, op, args);
      else arity_error(ERR_ARITY_SYNTAX, op, args);
    return a;
  }
```

186. arity_next, given the remainder of the arguments that were returned from arity, checks whether another one is present and whether it's allowed to be, then returns a value suitable for another call to arity_next.

```
 \begin{array}{l} \textbf{cell } \textit{arity\_next}(\textbf{cell } \textit{op}, \textbf{cell } \textit{args}, \textbf{cell } \textit{more}, \textbf{boolean } \textit{required\_p}, \textbf{boolean } \textit{last\_p}) \\ \{ & \textbf{if } (\textit{null\_p}(\textit{more})) \text{ } \{ \\ & \textbf{if } (\textit{required\_p}) \text{ } \textit{arity\_error}(\texttt{ERR\_ARITY\_MISSING}, \textit{op}, \textit{args}); \\ & \textbf{else } \text{ } \{ \\ & \textit{cts\_push}(\texttt{UNDEFINED}); \\ & \textbf{return } \texttt{NIL}; \\ & \} \\ \} & \textbf{else } \textbf{if } (\neg \textit{pair\_p}(\textit{more})) \\ & \textit{arity\_error}(\texttt{ERR\_ARITY\_SYNTAX}, \textit{op}, \textit{args}); \\ & \textbf{else } \textbf{if } (\textit{last\_p} \land \neg \textit{null\_p}(\textit{cdr}(\textit{more}))) \text{ } \{ \\ & \textbf{if } (\textit{operative\_p}(\textit{op}) \land \textit{pair\_p}(\textit{cdr}(\textit{more}))) \text{ } \textit{arity\_error}(\texttt{ERR\_ARITY\_EXTRA}, \textit{op}, \textit{args}); \\ & \textbf{else } \textit{arity\_error}(\texttt{ERR\_ARITY\_SYNTAX}, \textit{op}, \textit{args}); \\ \} \\ & \textit{cts\_push}(\textit{car}(\textit{more})); \\ & \textbf{return } \textit{cdr}(\textit{more}); \\ \} \\ \end{aligned}
```

187. closure bodies, and the contents of a begin expression, are compiled by simply walking the list and recursing into compile_expression for everything on it. When compiling the last item in the list the tail_p flag is raised so that the expression can use OP_APPLY_TAIL if appropriate, making tail recursion proper.

```
void compile_list(cell op, cell sexp, boolean tail_p)
  boolean t;
  cell body, next, this;
  body = undot(sexp);
  t = null\_p(body);
  if (t) {
     emitq(VOID);
     return;
  while (\neg t) {
     if (\neg pair\_p(body)) arity_error(ERR_ARITY_SYNTAX, op, sexp);
     \mathbf{this} = car(body);
     next = undot(cdr(body));
     t = null_p(next);
     compile\_expression(\mathbf{this}, t \land tail\_p);
     body = next;
}
```

- Closures (Applicatives & Operatives). The first thing to understand is that at their core applicatives and operatives work in largely the same way and have the same internal representation:
- The static *environment* which will expand into a local *environment* when entering the *closure*. This is where the variables that were "closed over" are stored.
 - The program which the *closure* will perform, as compiled bytecode and a starting instruction pointer.
- A list of formals naming any arguments which will be passed to the closure, so that they can be put into the newly-extended environment.

Entering a closure means extracting these saved values and restoring them to the virtual machine's registers, Env. Prog & Ip.

A closure can (usually does) have arguments and it's how they're handled that differentiates an applicative from an operative.

189. The main type of closure everyone is familiar with already even if they don't know it is a function 1 or applicative.

An applicative is created in response to evaluating a lambda expression. The bytecode which does this evaluating is created by *compile_lambda*.

```
void compile_lambda(cell op, cell args, boolean tail_p)
  cell body, in, formals, f;
  int begin_address, comefrom_end;
  body = arity(op, args, 1, btrue);
  body = undot(body);
  formals = cts\_pop();
  formals = undot(formals);
  if (\neg symbol\_p(formals)) {\langle Process lambda formals 190 \rangle \}
                     /* push formals onto the stack */
  emitq(formals);
  emitop(OP_PUSH);
  emitop(OP_LAMBDA);
                          /* create the applicative */
  begin\_address = comefrom();
                                   /* start address; argument to OP_LAMBDA */
  emitop(OP_JUMP);
                        /* jump over the compiled closure body */
  comefrom\_end = comefrom();
  patch(begin_address, int_new(Here));
                                 /* compile the code that entering the closure will interpret */
  compile\_list(op, body, tail\_p);
  emitop(OP_RETURN);
                          /* returns from the closure at run-time */
  patch(comefrom_end, int_new(Here));
```

¹ The word "function" is horribly misused everywhere and this trend will continue without my getting in its way.

190. If the *formals* given in the **lambda** expression are not in fact a single *symbol* then it must be a list of *symbols* which is verified here. At the same time if the list is a dotted pair then the *syntax* wrapper is removed.

```
#define find\_formal\_duplicates(n, h)
          if (symbol_p(n))
            for (cell d = (h); \neg null\_p(d); d = cdr(d))
               if (car(d) \equiv (n)) arity_error(ERR_ARITY_SYNTAX, op, args);
\langle \text{Process lambda formals } 190 \rangle \equiv
  cts\_push(f = cons(NIL, NIL));
  in = formals;
  while (pair_p(in)) {
     if (\neg symbol\_p(car(in)) \land \neg false\_p(car(in))) arity_error(ERR_ARITY_SYNTAX, op, args);
     find\_formal\_duplicates(car(in), cdr(cts\_ref()));
     cdr(f) = cons(car(in), NIL);
     f = cdr(f);
     in = undot(cdr(in));
  if (\neg null\_p(in)) {
     if (\neg symbol\_p(in) \land \neg false\_p(in)) arity_error(ERR_ARITY_SYNTAX, op, args);
     find\_formal\_duplicates(in, cdr(cts\_ref()));
     cdr(f) = in;
  formals = cdr(cts\_pop());
This code is used in section 189.
```

191. To enter this *closure* at run-time—aka. to call the function returned by lambda—the arguments it's called with must be evaluated (after being arity checked) then OP_APPLY or OP_APPLY_TAIL enters the *closure*, consuming a stack *frame* in the latter case.

The arguments and the formals saved in the *applicative* are walked together and saved in *direct*. If the formals list ends in a dotted *pair* then the remainder of the arguments are saved in *collect*.

When *collect* and *direct* have been prepared, being a copy of the unevaluated arguments in reverse order, they are walked again to emit the opcodes which will evaluate each argument and put the results onto the stack.

```
\langle Compile applicative combiner 191\rangle \equiv
  cell collect, direct, formals, a;
  int nargs = 0;
  formals = applicative\_formals(combiner);
  cts\_push(direct = NIL);
  a = undot(args);
  (Look for required arguments 192)
  (Look for optional arguments 193)
  if (pair_p(a)) arity_error(ERR_ARITY_EXTRA, combiner, args);
  \mathbf{else} \ \mathbf{if} \ (\neg null\_p(a)) \ \mathit{arity\_error}(\mathtt{ERR\_ARITY\_SYNTAX}, \mathit{combiner}, \mathit{args});
  (Evaluate optional arguments into a list 195)
  (Evaluate required arguments onto the stack 194)
  cts_clear();
  emitop(tail_p ? OP_APPLY_TAIL : OP_APPLY);
  emit(combiner);
This code is used in section 178.
```

192. It's a syntax error if the arguments are not a proper list, otherwise there is nothing much to say about this.

```
 \begin{array}{l} \langle \operatorname{Look} \ \text{for} \ \operatorname{required} \ \operatorname{arguments} \ 192 \rangle \equiv \\ & \mathbf{while} \ (pair\_p(formals)) \ \{ \\ & \mathbf{if} \ (\neg pair\_p(a)) \ \{ \\ & \mathbf{if} \ (null\_p(a)) \ arity\_error(\operatorname{ERR\_ARITY\_SYNTAX}, combiner, args); \\ & \mathbf{else} \ arity\_error(\operatorname{ERR\_ARITY\_SYNTAX}, combiner, args); \\ \} \\ & direct = cons(car(a), direct); \\ & cts\_set(direct); \\ & a = undot(cdr(a)); \\ & formals = cdr(formals); \\ & nargs + +; \\ \} \\ \end{array}  This code is used in section 191.
```

193. If the *applicative* formals indicate that it can be called with a varying number of arguments then that counts as one more argument which will be a list of whatever arguments remain.

This code is used in section 191.

194. To perform the evaluation, each argument in the (now reversed) list *direct* is compiled followed by an OP_PUSH to save the result on the stack.

```
 \begin{split} &\langle \text{ Evaluate required arguments onto the stack } 194 \rangle \equiv \\ & \textbf{while } (\neg null\_p(direct)) \; \{ \\ & compile\_expression(car(direct), 0); \\ & emitop(\texttt{OP\_PUSH}); \\ & direct = cdr(direct); \\ & \} \end{split}  This code is used in section 191.
```

195. If the *applicative* expects a varying number of arguments then the (also reversed) list in *collect* is compiled in the same way but before OP_PUSH, OP_CONS removes the growing list from the stack and prepends the new result to it and it's this *list* which is pushed.

```
 \begin{split} &\langle \, \text{Evaluate optional arguments into a } \mathit{list} \  \, 195 \, \rangle \equiv \\ & \quad \text{if } (\mathit{symbol\_p(formals)}) \  \, \{ \\ & \quad \mathit{emitop}(\mathtt{OP\_NIL}); \\ & \quad \text{while } (\neg \mathit{null\_p(collect)}) \  \, \{ \\ & \quad \mathit{compile\_expression}(\mathit{car(collect)}, 0); \\ & \quad \mathit{emitop}(\mathtt{OP\_CONS}); \\ & \quad \mathit{emitop}(\mathtt{OP\_PUSH}); \\ & \quad \mathit{collect} = \mathit{cdr}(\mathit{collect}); \\ & \quad \} \\ & \quad \mathit{cts\_clear}(\,); \\ & \quad \} \end{split}  This code is used in section 191.
```

196. Analogous to *compile_lambda* for *applicatives* is *compile_vov* for *operatives*. An *operative closure* is a simpler than an *applicative* because the arguments are not evaluated. Instead *compile_vov* needs to handle **vov**'s very different way of specifying its formals.

Resembling let rather than lambda, vov's formals specify what run-time detail the operative needs: The unevaluated arguments, the active environment and/or (unimplemented) a continuation delimiter. To do this each entry in the formals list is an association pair with the symbolic name for that detail associated with another symbol specifying what: vov/arguments, vov/environment or vov/continuation. Because no-one wants RSI these have the abbreviations vov/args, vov/env and vov/cont.

```
⟨ Global variables 6⟩ +≡
cell Sym_vov_args = UNDEFINED;
cell Sym_vov_args_long = UNDEFINED;
cell Sym_vov_cont = UNDEFINED;
cell Sym_vov_cont_long = UNDEFINED;
cell Sym_vov_env = UNDEFINED;
cell Sym_vov_env_long = UNDEFINED;
cell Sym_vov_env_long = UNDEFINED;

197. ⟨ Global initialisation 3⟩ +≡
Sym_vov_args = sym("vov/args");
Sym_vov_args_long = sym("vov/arguments");
Sym_vov_cont = sym("vov/cont");
Sym_vov_cont_long = sym("vov/continuation");
Sym_vov_env = sym("vov/env");
Sym_vov_env_long = sym("vov/environment");
```

```
198.
      void compile_vov(cell op, cell args, boolean tail_p)
    cell body, formals;
    int begin_address, comefrom_end;
    cell a = NIL;
    cell c = NIL:
    cell e = NIL;
    body = arity(op, args, 1, 1);
    body = undot(body);
    formals = cts\_pop();
    formals = undot(formals);
    (Scan operative informals 199)
                       /* push formals onto the stack */
    emitop(OP_NIL);
    emitq(c); emitop(OP\_CONS); emitop(OP\_PUSH);
    emitq(e); emitop(OP\_CONS); emitop(OP\_PUSH);
    emitq(a); emitop(OP\_CONS); emitop(OP\_PUSH);
    emitop(OP_VOV);
                       /* create the operative */
      /* The rest of compile_vov is identical to compile_lambda: */
    begin\_address = comefrom(); /* start address; argument to opcode */
    emitop(OP\_JUMP);
                          /* jump over the compiled closure body */
    comefrom\_end = comefrom();
    patch(begin_address, int_new(Here));
                                    /* compile the code that entering the closure will interpret */
    compile\_list(op, body, tail\_p);
    emitop(OP_RETURN);
                           /* return from the run-time closure */
    patch(comefrom_end, int_new(Here));
                                             /* finish building the closure */
  }
```

199. To scan the "informals" three variables, a, c and e are prepared with NIL representing the symbol for the arguments, continuation and environment respectively. Each "informal" is checked in turn using arity and the appropriate placeholder's NIL replaced with the symbol.

```
\langle Scan operative informals 199 \rangle \equiv
  cell r, s;
  if (\neg pair\_p(formals)) arity\_error(ERR\_ARITY\_SYNTAX, op, args);
\#define CHECK_AND_ASSIGN(v)
     if (\neg null\_p(v)) arity_error(ERR_ARITY_SYNTAX, op, args);
     (v) = s;
  while (pair_p(formals)) {
     arity(op, car(formals), 2, 0);
     r = cts\_pop();
     s = cts\_pop();
     if (\neg symbol\_p(s)) arity_error (ERR_ARITY_SYNTAX, op, args);
     else if (r \equiv Sym\_vov\_args \lor r \equiv Sym\_vov\_args\_long) CHECK_AND_ASSIGN(a)
     else if (r \equiv Sym\_vov\_env \lor r \equiv Sym\_vov\_env\_long) CHECK_AND_ASSIGN(e)
     else if (r \equiv Sym\_vov\_cont \lor r \equiv Sym\_vov\_cont\_long) CHECK_AND_ASSIGN(c)
     formals = cdr(formals);
  if (\neg null\_p(formals)) arity\_error(ERR\_ARITY\_SYNTAX, op, args);
This code is used in section 198.
```

200. Entering an *operative* involves pushing the 3 desired run-time properties, or NIL, onto the stack as though arguments to an *applicative closure* (remember that the unevaluated run-time arguments of the *closure* are potentially one of those run-time properties).

```
\langle Compile operative combiner 200\rangle \equiv
  cell a, c, e, f;
  f = operative\_formals(combiner);
  a = \neg null_{-p}(car(f)); f = cdr(f);
  e = \neg null\_p(car(f)); \ f = cdr(f);
  c = \neg null\_p(car(f)); f = cdr(f);
  if (c) error (ERR_UNIMPLEMENTED, NIL);
  else emitop(OP_NIL);
  if (e) {
    emitop(OP_ENV_QUOTE);
    emitop(OP_PUSH);
  else emitop(OP_NIL);
  if (a) {
    emitq(args);
    emitop(\mathtt{OP\_PUSH});
  else emitop(OP_NIL);
  emitop(tail_p ? OP_APPLY_TAIL : OP_APPLY);
  emit(combiner);
This code is used in section 178.
```

201. Conditionals (if). Although you could define a whole language with just lambda and **vov**¹ that way lies Church Numerals and other madness, so we will define the basic conditional, if.

```
void compile_conditional(cell op, cell args, boolean tail_p)
  cell alternate, condition, consequent, more;
  int \ \mathit{jump\_false} \,, \ \mathit{jump\_true} \,;
  more = arity(op, args, 2, 1);
  arity\_next(op, args, more, 0, 1);
  alternate = cts\_pop();
  consequent = cts\_pop();
  condition = cts\_pop();
  compile\_expression(condition, 0);
  emitop(OP_JUMP_FALSE);
  jump\_false = comefrom();
  compile\_expression(consequent, tail\_p);
  emitop(OP_JUMP);
  jump\_true = comefrom();
  patch(jump_false, int_new(Here));
  if (undefined_p(alternate)) emitq(VOID);
  else compile_expression(alternate, tail_p);
  patch(jump_true, int_new(Here));
```

 $^{^{1}}$ In fact I think conditionals can be achieved in both somehow, so you only need one.

202. Run-time Evaluation (eval). eval must evaluate its 1 or 2 arguments in the current environment, and then enter the environment described by the second to execute the program in the first.

```
void compile_eval(cell op, cell args, boolean tail_pll_unused)
  cell more, sexp, eenv;
  int goto\_env\_p;
  more = arity(op, args, 1, btrue);
  sexp = cts\_pop();
  arity\_next(op, args, more, bfalse, btrue);
  eenv = cts\_pop();
  if (\neg undefined\_p(eenv)) {
    compile\_expression(eenv, 0);
    emitop(OP_PUSH);
    emitop(OP_ENVIRONMENT_P);
    emitop(OP_JUMP_TRUE);
    goto\_env\_p = comefrom();
    emitq(Sym_ERR_UNEXPECTED);
    emitop(OP_ERROR);
    patch(goto\_env\_p, int\_new(Here));
  compile\_expression(sexp, 0);
  emitop(OP_COMPILE);
  emitop(undefined_p(eenv) ? OP_RUN : OP_RUN_THERE);
```

203. Run-time Errors. error expects a symbol an the first position and an optional form to evaluate in the second.

```
 \begin{array}{l} \textbf{void} \ compile\_error(\textbf{cell} \ op, \textbf{cell} \ args, \textbf{boolean} \ tail\_p \ ll\_unused) \\ \{ \\ \textbf{cell} \ id, \ more, \ value; \\ more = arity(op, args, 1, 1); \\ arity\_next(op, args, more, 0, 1); \\ value = cts\_pop(); \\ id = cts\_pop(); \\ if \ (\neg symbol\_p(id)) \ arity\_error(\texttt{ERR\_ARITY\_SYNTAX}, op, args); \\ if \ (undefined\_p(value)) \ emitq(\texttt{NIL}); \\ \textbf{else} \ compile\_expression(value, 0); \\ emitop(\texttt{OP\_PUSH}); \\ emitop(\texttt{OP\_ERROR}); \\ \} \end{array}
```

204. Cons Cells. These operators have been written out directly despite the obvious potential for refactoring into reusable pieces. This is short-lived until more compiler routines have been written and the similarity patterns between them become apparent.

Cons cells are defined by the cons, car, cdr, null? and pair? symbols with set-car! and set-cdr! providing for mutation.

```
\mathbf{void}\ \mathit{compile\_cons}(\mathbf{cell}\ \mathit{op}, \mathbf{cell}\ \mathit{args}, \mathbf{boolean}\ \mathit{tail\_pll\_unused})
      /* pattern 0; arity \equiv (O, O) */
  cell ncar, ncdr;
  arity(op, args, 2, 0);
  ncdr = cts\_pop();
  ncar = cts\_pop();
  compile\_expression(ncdr, 0);
  emitop(OP_PUSH);
  compile\_expression(ncar, 0);
  emitop(OP_CONS);
void compile_car(cell op, cell args, boolean tail_pll_unused)
      /* pattern 1; arity = (OP\_PAIR\_P) */
  int comefrom_pair_p;
  arity(op, args, 1, 0);
  compile\_expression(cts\_pop(), 0);
  emitop(OP_PUSH);
  emitop(OP_PAIR_P);
  emitop(OP_JUMP_TRUE);
  comefrom\_pair\_p = Here;
  emit(NIL);
                                            /* TODO */
  emitq(Sym\_ERR\_UNEXPECTED);
  emitop(OP_ERROR);
  patch(comefrom\_pair\_p, int\_new(Here));
  emitop(OP_POP);
  emitop(OP_CAR);
void compile_cdr(cell op, cell args, boolean tail_pll_unused)
  int comefrom_pair_p;
  arity(op, args, 1, 0);
  compile\_expression(cts\_pop(), 0);
  emitop(OP_PUSH);
  emitop(OP_PAIR_P);
  emitop(\mathtt{OP\_JUMP\_TRUE});
  comefrom\_pair\_p = Here;
  emit(NIL);
  emitq(Sym_ERR_UNEXPECTED);
                                            /* TODO */
  emitop(OP_ERROR);
  patch(comefrom\_pair\_p, int\_new(Here));
  emitop(OP_POP);
                        /* this is the only difference from the above */
  emitop(OP\_CDR);
void compile_null_p(cell op, cell args, boolean tail_p ll_unused)
      /* pattern 2 = predicate */
```

```
arity(op, args, 1, 0);
  compile\_expression(cts\_pop(), 0);
  emitop(OP_NULL_P);
void compile_pair_p(cell op, cell args, boolean tail_pll_unused)
  arity(op, args, 1, 0);
  compile\_expression(cts\_pop(), 0);
  emitop(OP\_PAIR\_P);
}
void compile_set_car_m(cell op, cell args, boolean tail_pll_unused)
     /* pattern 3 = arity = (OP_PAIR_P, O) */
  cell value, object;
  int goto_pair_p;
  arity(op, args, 2, 0);
  value = cts\_pop();
  object = cts\_pop();
  compile_expression(object, bfalse);
  emitop(OP_PUSH);
  emitop(OP_PAIR_P);
  emitop(OP_JUMP_TRUE);
  goto\_pair\_p = comefrom();
  emitq(Sym\_ERR\_UNEXPECTED);
  emitop(OP_ERROR);
  patch(goto\_pair\_p, int\_new(Here));
  compile_expression(value, bfalse);
  emitop(OP_SET_CAR_M);
void compile_set_cdr_m(cell op, cell args, boolean tail_pll_unused)
  cell value, object;
  \mathbf{int} \ goto\_pair\_p;
  arity(op, args, 2, 0);
  value = cts\_pop();
  object = cts\_pop();
  compile_expression(object, bfalse);
  emitop(OP_PUSH);
  emitop(OP_PAIR_P);
  emitop(OP_JUMP_TRUE);
  goto\_pair\_p = comefrom();
  emitq(Sym\_ERR\_UNEXPECTED);
  emitop(OP_ERROR);
  patch(goto_pair_p, int_new(Here));
  compile_expression(value, bfalse);
  emitop(OP_SET_CDR_M);
```

205. Environment. The *environment* mutators are the same except for the flag given to the final opcode.

```
void compile_set_m(cell op, cell args, boolean tail_pll_unused)
     /* pattern 4, arity = (OP_ENV_P \# <> symbol ?) */
  cell env, name, value;
  int goto_env_p;
  arity(op, args, 3, bfalse);
  value = cts\_pop();
  name = cts\_pop();
  env = cts\_pop();
  if (¬symbol_p(name)) error (ERR_ARITY_SYNTAX, NIL);
  compile_expression(env, bfalse);
  emitop(OP_PUSH);
  emitop(OP_ENVIRONMENT_P);
  emitop(OP_JUMP_TRUE);
  goto\_env\_p = comefrom();
  emitq(Sym\_ERR\_UNEXPECTED);
  emitop(OP_ERROR);
  patch(goto\_env\_p, int\_new(Here));
  compile_expression(value, bfalse);
  emitop(OP_ENV_MUTATE_M);
  emit(name);
  emit(FALSE);
void compile_define_m(cell op, cell args, boolean tail_pll_unused)
  cell env, name, value;
  int goto_env_p;
  arity(op, args, 3, bfalse);
  value = cts\_pop();
  name = cts\_pop();
  env = cts\_pop();
  if (\neg symbol\_p(name)) error (ERR_ARITY_SYNTAX, NIL);
  compile_expression(env, bfalse);
  emitop(OP_PUSH);
  emitop(\mathtt{OP\_ENVIRONMENT\_P});
  emitop(OP_JUMP_TRUE);
  goto\_env\_p = comefrom();
  emitq(Sym_ERR_UNEXPECTED);
  emitop(OP_ERROR);
  patch(goto_env_p, int_new(Here));
  compile_expression(value, bfalse);
  emitop(OP_ENV_MUTATE_M);
  emit(name);
  emit(TRUE);
void compile_env_root(cell op, cell args, boolean tail_pll_unused)
     /* pattern 5 = \text{no args } */
  arity(op, args, 0, bfalse);
  emitop(OP_ENV_ROOT);
```

```
 \begin{array}{l} \mathbf{void} \ \ compile\_env\_current(\mathbf{cell} \ op, \mathbf{cell} \ args, \mathbf{boolean} \ tail\_p \ ll\_unused) \\ \{ \\ \ \ arity(op, args, 0, bfalse); \\ \ \ emitop(\mathtt{OP\_ENV\_QUOTE}); \\ \} \end{array}
```

206. Quotation & Quasiquotation. A quoted object is one which is not evaluated and we have an opcode to do just that, used by many of the implementations above.

```
 \begin{array}{l} \mathbf{void} \ \ compile\_quote(\mathbf{cell} \ \ op \ ll\_unused, \mathbf{cell} \ \ args, \mathbf{boolean} \ \ tail\_p \ ll\_unused) \\ \{ \ \ emitq(args); \ \} \end{array}
```

207. Quasiquoting an object is almost, but not quite, entirely different. The end result is the same however—a run-time object which (almost) exactly matches the unevaluated source code that it was created from.

A quasiquoted object is converted into its final form by changing any unquote (and unquote-splicing) within it to the result of evaulating them. This is complicated enough because we're now writing a compiler within our compiler but additionally the quasiquoted object may contain quasiquoted objects, changing the nature of the inner-unquote operators.

208. The compiler for compiling quasiquoted code only calls directly into the recursive quasicompiler engine (let's call it the quasicompiler).

```
⟨ Function declarations 8⟩ +≡
void compile_quasicompiler(cell, cell, int, boolean);
209. void compile_quasiquote(cell op, cell args, boolean tail_pll_unused)
{ /* pattern Q */
compile_quasicompiler(op, args, args, 0, bfalse);
}
```

210. As with any compiler, the first task is to figure out what sort of expression is being quasicompiled. Atoms are themselves. Otherwise lists and vectors must be recursively compiled item-by-item, and the syntactic operators must operate when encountered.

Quasiquoting vectors is not supported but I'm not anticipating it being difficult, just not useful yet.

```
 \begin{array}{l} \textbf{void} \ compile\_quasicompiler(\textbf{cell} \ op, \textbf{cell} \ oargs, \textbf{cell} \ arg, \textbf{int} \ depth, \textbf{boolean} \ in\_list\_p) \\ \{ & \textbf{if} \ (pair\_p(arg)) \ \{ \ Quasiquote \ a \ pair/list \ 211 \rangle \} \\ & \textbf{else} \ \textbf{if} \ (vector\_p(arg)) \ \{ \ Quasiquote \ syntam \ 212 \rangle \} \\ & \textbf{else} \ \textbf{if} \ (syntam\_p(arg)) \ \{ \ Quasiquote \ syntam \ 212 \rangle \} \\ & \textbf{else} \ \{ \\ & emitq(arg); \\ & \textbf{if} \ (in\_list\_p) \ emitop(OP\_CONS); \\ \} \\ \} \end{array}
```

¹ Yo!

LossLess Programming Environment

88

211. Dealing first with the simple case of a list the quasicompiler reverses the list to find its tail, which may or may not be NIL, and recursively calling *compile_quasicompiler* for every item.

After each item has been quasicompiled it will be combined with the transformed list being grown on top of the stack.

When quasicompiling the list's tail there is no partial list to prepend it to so the quasicompiler is entered in atomic mode. compile_quasicompiler can be relied on to handle the tail of a proper or improper list.

```
\langle \text{Quasiquote a pair/list 211} \rangle \equiv
  cell todo, tail;
  tail = NIL;
  todo = list\_reverse(arg, \&tail, \Lambda);
  compile_quasicompiler(op, oargs, tail, depth, bfalse);
  for (; \neg null\_p(todo); todo = cdr(todo)) {
     emitop(OP_PUSH);
                               /* Push the list so far */
     compile\_quasicompiler(op, oargs, car(todo), depth, btrue);
  if (in\_list\_p) emitop(OP\_CONS);
This code is used in section 210.
```

The quote & unquote syntax is where the quasicompiler starts to get interesting. quotes and quasiquotes (and a dotted tail) recurse back into the quasicompiler to emit the transformation of the quoted object, then re-apply the syntax operator.

depth is increased when recursing into a quasiquote so that the compiler knows whether to evaluate an unquote operator.

```
\langle \text{ Quasiquote syntax } 212 \rangle \equiv
  int d;
  if (car(arq) \equiv Sym\_SYNTAX\_DOTTED
          \vee car(arg) \equiv Sym_SYNTAX_QUOTE
          \vee car(arg) \equiv Sym_SYNTAX_QUASI) {
     d = (car(arg) \equiv Sym\_SYNTAX\_QUASI) ? 1 : 0;
     compile\_quasicompiler(op, oargs, cdr(arg), depth + d, bfalse);
     emitop(OP_SYNTAX);
     emit(car(arg));
     if (in\_list\_p) emitop(OP\_CONS);
  }
See also sections 213 and 214.
This code is used in section 210.
```

213. unquote evaluates the unquoted object. If quasiquote is quasicompiling an inner quasiquote then the unquoted object isn't evaluated but compiled at a decreased depth. This enables the correct unquoting-or-not of quasiquoting quasiquoted quotes.

```
\langle \text{Quasiquote syntax } 212 \rangle + \equiv
  else
     if (car(arg) \equiv Sym\_SYNTAX\_UNQUOTE) {
        if (depth > 0) {
           compile\_quasicompiler(op, oargs, cdr(arg), depth - 1, bfalse);
           emitop(OP_SYNTAX);
           emit(Sym\_SYNTAX\_UNQUOTE);
        else compile\_expression(cdr(arg), bfalse);
         \textbf{if } (\textit{in\_list\_p}) \ \textit{emitop}(\texttt{OP\_CONS}); \\
     }
```

214. Similarly to *unquote*, *unquote-splicing* recurses back into the quasicompiler at a lower depth when unquoting an inner quasiquote.

```
 \begin{split} &\langle \text{Quasiquote syntax 212} \rangle + \equiv \\ & \text{else} \\ & \text{if } (car(arg) \equiv Sym\_SYNTAX\_UNSPLICE) \ \{ \\ & \text{if } (depth > 0) \ \{ \\ & compile\_quasicompiler(op, oargs, cdr(arg), depth - 1, bfalse); \\ & emitop(\texttt{OP\_SYNTAX}); \\ & emit(Sym\_SYNTAX\_UNSPLICE); \\ & \text{if } (in\_list\_p) \ emitop(\texttt{OP\_CONS}); \\ & \} \\ & \text{else } \{ \langle \text{Compile unquote-splicing 215} \rangle \} \\ & \} \\ & \text{else error } (\texttt{ERR\_UNIMPLEMENTED, NIL}); \end{split}
```

215. Splicing Lists. If not recursing back into the quasicompiler at a lower depth then we are quasicompiling at the lowest depth and need to do the work.

When splicing into the tail position of a list we can replace its NIL with the evaluation with minimal further processing. Unfortunately we don't know until run-time whether we are splicing into the tail position – consider constructs like '(,@foo ,@bar) where bar evaluates to NIL.

```
\langle Compile unquote-splicing 215\rangle \equiv
  \mathbf{int} \ \mathit{goto\_inject\_iterate}, \ \mathit{goto\_inject\_start}, \ \mathit{goto\_finish};
  int goto_list_p, goto_null_p, goto_nnull_p;
  if (\neg in\_list\_p) error (ERR_UNEXPECTED, arg);
  emitop(OP_PEEK);
  emitop(OP_NULL_P);
  emitop(OP\_JUMP\_TRUE); goto\_null\_p = comefrom();
  emitop(OP_PUSH);
                            /* save FALSE */
  emitop(OP\_JUMP); goto\_nnull\_p = comefrom();
  patch(goto\_null\_p, int\_new(Here));
  emitop(OP\_SWAP);
                            /* become the tail, save TRUE */
  patch(goto\_nnull\_p, int\_new(Here));
See also sections 216, 217, and 218.
This code is used in section 214.
```

216. FALSE or TRUE is now atop the stack indicating whether a new list is being built otherwise the remainder of the list is left on the stack. Now we can evaluate and validate the expression.

```
⟨ Compile unquote-splicing 215⟩ +≡
compile_expression(cdr(arg),0);
emitop(OP_PUSH);
emitop(OP_LIST_P); emit(TRUE); emit(FALSE);
emitop(OP_JUMP_TRUE); goto_list_p = comefrom();
emitq(Sym_ERR_UNEXPECTED);
emitop(OP_ERROR);
```

217. If we have a list we can leave it as-is if we were originally in the tail position.

```
 \begin{split} &\langle \operatorname{Compile \ unquote-splicing \ 215} \rangle +\equiv \\ &patch(goto\_list\_p, int\_new(Here)); \\ &emitop(OP\_POP); \\ &emitop(OP\_SWAP); \\ &emitop(OP\_JUMP\_TRUE); \ goto\_finish = comefrom(); \end{split}
```

218. Splicing a list into the middle of another list is done item-by-item in reverse. A small efficiency could be gained here by not walking the list a second time (the first to validate it above) at the cost of more complex bytecode.

By now the evaluated list to splice in is first on the stack followed by the partial result.

```
⟨ Compile unquote-splicing 215⟩ +≡
  emitop(OP_POP);
  emitop(OP_LIST_REVERSE); emit(TRUE); emit(FALSE);
  ⟨ Walk through the splicing list 219⟩
```

```
219. \langle Walk through the splicing list 219\rangle \equiv emitop(OP\_JUMP); goto\_inject\_start = comefrom(); goto\_inject\_iterate = Here; <math>emitop(OP\_POP); emitop(OP\_SNOC); emitop(OP\_CYCLE); emitop(OP\_CYCLE); emitop(OP\_CONS); emitop(OP\_SWAP); See also section 220. This code is used in section 218.
```

220. If this was the last item (the first of the evaluated list's) or the evaluation was NIL then we're done otherwise we go around again. This is also where the loop starts to handle the case of evaluating an empty list.

```
 \begin{tabular}{ll} $\langle$ Walk through the splicing list $219$ $\rangle$ $+$\equiv$ $patch(goto\_inject\_start, int\_new(Here))$; $emitop(OP\_PUSH)$; $emitop(OP\_NULL\_P)$; $emitop(OP\_JUMP\_FALSE)$; $emit(int\_new(goto\_inject\_iterate))$; $emitop(OP\_POP)$; $patch(goto\_finish, int\_new(Here))$; $emitop(OP\_POP)$; $emitop
```

A comprehensive test suite is planned for LossLess but a testing tool would be no good if it wasn't itself reliable, which these primarily unit tests work towards. In addition to the main library lossless.o two libraries with extra functionality needed by the tests are created: t/lltest.o and t/llalloc.o which additionally to extra operators wraps reallocarray to test memory allocation.

```
\langle t/lltest.c 221 \rangle \equiv
#define LL_TEST
#include "../lossless.c"
                                    /* C source */
222. \langle Global variables 6\rangle + \equiv
#ifdef LL_TEST
  int Allocate\_Success = -1;
#endif
223. \langle Externalised global variables 7 \rangle + \equiv
#ifdef LL_TEST
  extern int Allocate_Success;
#endif
224. \langle t/llalloc.c 224 \rangle \equiv
#define LL_ALLOCATE fallible_reallocarray
  (System headers 4)
  void *fallible_reallocarray(void *, size_t, size_t);
#define LL_TEST
#include "../lossless.c"
                                      /* C source */
  void *fallible_reallocarray(void *ptr, size_t nmemb, size_t size)
     return Allocate\_Success ---? reallocarray(ptr, nmemb, size) : <math>\Lambda;
        Tests need to be able to save data from the maw of the garbage collector.
\langle \text{Global variables } 6 \rangle + \equiv
  cell Tmp_{-}Test = NIL;
226. \langle Externalised global variables 7 \rangle + \equiv
  extern cell Tmp_{-}Test;
227. \langle Protected Globals 21 \rangle + \equiv
#ifdef LL_TEST
  & Tmp\_Test,
#endif
228. \langle \text{Pre-initialise } Small\_Int \& \text{ other gc-sensitive buffers } 15 \rangle + \equiv
#ifdef LL_TEST
  Tmp_{-}Test = NIL;
#endif
```

229. Utilities: dynamic memory. Unit tests allocate memory with the malloc(1) family of allocators from C's standard library to avoid clashing with the LossLess heap which is under test. This is a simple memory manager which is designed solely for buffers which can grow but are never likely to be deallocated.

The data pointer is a **char** * rather than the more appropriate **void** * because these buffers are mostly used to store C-strings or an *llt_Fixture* buffer (defined later) for which there's a few macros.

Because this allocator will be used exclusively by the test code to allocate small buffers, primarily for small pieces of text, no especial care is taken to guard against any errors beyond memory exhaustion.

```
#define bfixn(f,n) ( ( llt_Fixture * ) ((f)\neg data) ) [(n)]
#define bfix\theta(f) bfixn((f),(f)\rightarrow len-2)
#define bfix1(f) bfixn((f),(f)\rightarrow len-1)
#define bfix bfix1
\langle \text{Type definitions 5} \rangle + \equiv
  typedef struct {
     size_t len;
     size_t size;
     char data[];
  } llt_buffer;
230. \langle Function declarations \rangle + \equiv
  llt\_buffer * llt\_alloc\_imp(size\_t, size\_t);
  llt_buffer * llt_cat(const char *, ...);
  llt_buffer *llt_grow_imp(llt_buffer *, size_t);
        #define llt\_alloc(l,t) llt\_alloc\_imp((l), sizeof(t))
  llt_buffer *llt_alloc_imp(size_t len, size_t size)
     llt_buffer *r;
     size_t total;
     total = (len * size) + sizeof(llt_buffer);
     ERR_OOM_P(r = calloc(total, 1));
     r \rightarrow len = len;
     r \rightarrow size = size;
     return r;
  }
        #define llt\_grow(o, d) ((o) = llt\_grow\_imp((o), (o) \neg len + (d)))
  llt_buffer *llt_grow_imp(llt_buffer *old, size_t len)
     llt_buffer *new;
     size_t ntotal;
     ntotal = (len * old \neg size) + sizeof(llt_buffer);
     ERR_00M_P(new = realloc(old, ntotal));
     bzero((\mathbf{char}\ *)\ \mathbf{new} + \mathbf{sizeof}(\mathbf{llt\_buffer}) + (\mathbf{new} \neg size\ *\ \mathbf{new} \neg len), \mathbf{new} \neg size\ *\ (len-\mathbf{new} \neg len));
     \mathbf{new} \neg len = len;
     return new;
```

233. Every application should come with a cat. This one should soon start hunting down badly tangled test strings.

```
\begin{split} &\textbf{llt\_buffer} * llt\_cat(\textbf{const char} * fmt, \ldots) \\ & \\ & \textbf{llt\_buffer} * r = llt\_alloc(0, \textbf{char}); \\ & \textbf{int } ret = -1; \\ & \textbf{va\_list } ap; \\ & va\_start(ap, fmt); \\ & \textbf{while } (ret < 0 \lor r \neg data[r \neg len - 1]) \ \{ \\ & llt\_grow(r, \texttt{BUFFER\_SEGMENT}); \\ & ret = vsnprintf(r \neg data, r \neg len, fmt, ap); \\ & \} \\ & va\_end(ap); \\ & \textbf{return } r; \\ & \} \end{split}
```

234. Utilities: Serialisation. Some tests need to see if an object in memory has changed at all and often in ways which could not be detected with high-level comparisons so these functions serialise and compare the full internal representation of an object. The offset of a *vector* in its pool can change legitimately so this is not included in the serialisation except when vector garbage collection is under test.

```
\langle Function declarations \rangle + \equiv
  llt_buffer *llt_serialise(cell, boolean);
  boolean llt_compare_serial(llt_buffer *, cell, boolean);
  llt_buffer *llt_copy_refs(cell);
236.
        #define llt_extend_serial(buf, by, off) do
             llt_buffer *q = (by);
             llt\_grow((buf), q \rightarrow len);
             bcopy(q \rightarrow data, (buf) \rightarrow data + ((off) * q \rightarrow size), q \rightarrow len * q \rightarrow size);
             (off) += q \rightarrow len;
             free(q);
          while (0)
  llt_buffer *llt_serialise(cell obj, boolean offset_p)
     int i;
     size_t off;
     llt_buffer *r;
     r = llt\_alloc(\mathbf{sizeof(cell), char});
     *(\mathbf{cell} *) r \rightarrow data = obj;
     off = sizeof(cell);
     if (special_p(obj)) return r;
     llt\_grow(r, sizeof(char) + (sizeof(cell) * 2));
     bcopy(\&tag(obj), r \neg data + off, \mathbf{sizeof(char)});
     off += 1:
     if (vector_p(obj)) bzero(r \rightarrow data + off, sizeof(cell));
     else bcopy(\&car(obj), r \rightarrow data + off, sizeof(cell));
     off += sizeof(cell);
     if (vector_p(obj) \land \neg offset_p) bzero(r \neg data + off, sizeof(cell));
     else bcopy(\&cdr(obj), r \rightarrow data + off, sizeof(cell));
     off += sizeof(cell);
     if (acar\_p(obj)) llt\_extend\_serial(r, llt\_serialise(car(obj), offset\_p), off);
     if (acdr_p(obj)) llt_extend_serial(r, llt_serialise(cdr(obj), offset_p), off);
     if (vector_p(obj)) {
        llt\_grow(r, sizeof(cell) * VECTOR\_HEAD);
        for (i = 1; i \leq VECTOR\_HEAD; i++) {
           bcopy(\&vector\_ref(obj, -i), r \neg data + off, sizeof(cell));
           off += sizeof(cell);
        for (i = 0; i < vector\_length(obj); i++)
           llt\_extend\_serial(r, llt\_serialise(vector\_ref(obj, i), offset\_p), off);
     return r;
  }
```

LossLess Programming Environment

```
237. llt_buffer *llt_copy_refs(cell obj)
   {
      size_t \ off = sizeof(cell);
      llt\_buffer *r = llt\_alloc(1, cell);
      *(\mathbf{cell} *) r \rightarrow data = obj;
      if (acar\_p(obj)) llt\_extend\_serial(r, llt\_copy\_refs(car(obj)), off);
      if (acdr_p(obj)) llt_extend_serial(r, llt_copy_refs(cdr(obj)), off);
      return r;
   }
\textbf{238.} \quad \textbf{boolean} \ \textit{llt\_compare\_serial} (\textbf{llt\_buffer} *\textit{buf1}, \textbf{cell} \ \textit{obj}, \textbf{boolean} \ \textit{offset\_p})
      boolean r;
      llt_buffer *buf2;
      buf2 = llt\_serialise(obj, offset\_p);
      if (buf1 \rightarrow len \neq buf2 \rightarrow len) {
         free(buf2);
         {\bf return}\ \textit{bfalse};
      r = (bcmp(buf1, buf2, buf1 \neg len) \equiv 0)? btrue : bfalse;
      free(buf2);
      return r;
```

239. Utilities: TAP. The Perl ecosystem has a well-deserved reputation for its thorough testing regime and the quality (if not necessarily the quality) of the results so LossLess is deliberately aping the interfaces that were developed there.

The LossLess internal tests are a collection of test "script"s each of which massages some LossLess function or other and then reports what happened in a series of binary pass/fail "test"s. A test in this sense isn't the performance of any activity but comparing the result of having already performed some activity with the expected outcome. Any one action normally requires a lot of individual tests to confirm the validity of its result. Occasionally "test" refers to a collection of these tests which are performed together, which is a bad habit.

This design is modelled on the Test Anything Protocol and the test scripts call an API that looks suspiciously like a tiny version of *Test::Simple*.

 tap_plan is optionally called before the test script starts if the total number of tests is known in advance and then again at the end of testing with an argument of 0 to emit exactly one test plan.

```
#define tap\_fail(m) tap\_ok(bfalse,(m))
#define tap_pass(m) tap_ok(btrue, (m))
#define tap\_again(t, r, m) tap\_ok(((t) = ((t) \land (r))), (m))
                                                                        /* intentional assignment */
#define tap\_more(t, r, m) (t) &= tap\_ok((r), (m))
\langle Function declarations \rangle + \equiv
#ifdef LL_TEST
  void tap_plan(int);
  boolean tap\_ok(boolean, char *);
  \mathbf{int} \ \mathit{test\_count\_free\_list}(\mathbf{void});
  char *test\_msqf(char *, char *, char *, ...);
  void test_vm_state(char *, int);
#endif
240. \langle Global variables 6\rangle + \equiv
  boolean Test\_Passing = btrue;
  int Test_Plan = -1;
                            /* \text{ not } 0 */
  int Next_{-}Test = 1;
        \langle Externalised global variables 7 \rangle + \equiv
  extern int Test_Plan, Next_Test;
242. void tap_{-}plan(int plan)
     if (plan \equiv 0) {
       if (Test\_Plan < 0) printf("1..%d\n", Next\_Test - 1);
       else if (Next\_Test - 1 \neq Test\_Plan) {
          printf("\#_\square Planned_\square\%3\$d_\square\%1\$s_\square but_\square ran_\square\%2\$s_\%4\$d! n", (Test_Plan \equiv 1? "test" : "tests"),
               (Next\_Test \le Test\_Plan ? "only\_" : ""), Test\_Plan, Next\_Test - 1);
          Test\_Passing = bfalse;
       }
       return:
     if (Test_Plan > 0) error ("plan-exists", int_new(Test_Plan));
     if (plan < 0) error (ERR_UNEXPECTED, cons(sym("test-plan"), int_new(plan)));
     Test\_Plan = plan;
     printf("1..%d\n", plan);
```

LossLess Programming Environment

98

```
243. boolean tap\_ok(boolean result, char *message)
    printf("%s_{\sqcup}%d_{\sqcup}%s\n",(result?"ok":"not_{\sqcup}ok"),
         Next\_Test +++,
         (message \land *message) ? message : "?");
    if (result) return btrue;
    return Test\_Passing = bfalse;
```

244. LossLess is a programming language and so a lot of its tests involve code. test_vmsqf formats messages describing tests which involve code (or any other s-expression) in a consistent way. The caller is expected to maintain its own buffer of TEST_BUFSIZE bytes a pointer to which goes in and out so that the function can be used in-line.

tmsgf hardcodes the names of the variables a function passes into test_vmsgf for brevity.

```
#define TEST_BUFSIZE 1024
\langle Complex definitions & macros 146\rangle + \equiv
\#define tmsgf(...) test\_msgf (msg, prefix, \_\_VA\_ARGS\_\_)
245. \mathbf{char} * test\_msgf(\mathbf{char} * tmsg, \mathbf{char} * tsrc, \mathbf{char} * fmt, \dots)
        /* TODO: feed this to the cat */
     char ttmp[TEST_BUFSIZE] = \{0\};
     int ret;
     va_list ap;
     va\_start(ap, fmt);
     ret = vsnprintf(ttmp, TEST\_BUFSIZE, fmt, ap);
     va_-end(ap);
     snprintf(tmsg, TEST\_BUFSIZE, "%s: \_ %s", tsrc, ttmp);
     return tmsg;
```

emitop(OP_PUSH); emitq(arqs);

}

 $emitop(\mathtt{OP_TEST_PROBE});$

§246 LossLess Programming Environment **246**. Utilities: test!probe. Some tests need to examine a snapshot of the interpreter's run-time state which they do by calling test!probe. \langle Function declarations $\rangle + \equiv$ void compile_testing_probe(cell, cell, boolean); void compile_testing_probe_app(cell, cell, boolean); **cell** testing_build_probe(**cell**); \langle Testing opcode names 247 $\rangle \equiv$ 247.OP_TEST_PROBE , This code is used in sections 146 and 147. **248.** \langle Testing opcodes $248 \rangle \equiv$ $[OP_TEST_PROBE] = \{ . name = "OP_VOV", . nargs = 1 \},$ This code is used in section 150. **249.** \langle Testing implementations $249 \rangle \equiv$ case OP_TEST_PROBE: $Acc = testing_build_probe(rts_pop(1));$ skip(1);break; This code is used in section 110. **250.** \langle Testing primitives $250 \rangle \equiv$ {"test!probe", compile_testing_probe}, {"test!probe-applying", compile_testing_probe_app}, This code is used in section 517. **251.** #define $probe_push(n, o)$ do $vms_push(cons((o), NIL));$ $vms_set(cons(sym(n), vms_ref()));$ $t = vms_pop();$ $vms_set(cons(t, vms_ref()));$ while (0)**cell** testing_build_probe(**cell** was_Acc) $\mathbf{cell}\ t;$ $vms_-push(NIL);$ probe_push("Acc", was_Acc); probe_push("Args", Acc); $probe_push("Env", Env);$ return vms_pop(); } void compile_testing_probe(cell opll_unused, cell args, boolean tail_pll_unused)

}

This variant evaluates its run-time arguments first. void compile_testing_probe_app(cell opll_unused, cell args, boolean tail_pll_unused) emitop(OP_PUSH); $cts_push(args = list_reverse(args, \Lambda, \Lambda));$ emitq(NIL); for $(; pair_p(args); args = cdr(args))$ { emitop(OP_PUSH); $compile_expression(car(args), bfalse);$ emitop(OP_CONS); $cts_pop();$ emitop(OP_TEST_PROBE); } 254. Utilities: VM State. Many tests validate some parts of the VM state. Which parts is controlled by the *flags* parameter. #define TEST_VMSTATE_RUNNING #01 #define TEST_VMSTATE_NOT_RUNNING #00 #define TEST_VMSTATE_INTERRUPTED #02 #define TEST_VMSTATE_NOT_INTERRUPTED #00 #define TEST_VMSTATE_VMS #04 #define TEST_VMSTATE_CTS #08 #define TEST_VMSTATE_RTS #10 #define TEST_VMSTATE_STACKS (TEST_VMSTATE_VMS | TEST_VMSTATE_CTS | TEST_VMSTATE_RTS) #define TEST_VMSTATE_ENV_ROOT #20 #define TEST_VMSTATE_PROG_MAIN #40 #define $test_vm_state_full(p)$ $test_vm_state((p), \texttt{TEST_VMSTATE_NOT_RUNNING} \mid \texttt{TEST_VMSTATE_NOT_INTERRUPTED} \mid$ TEST_VMSTATE_ENV_ROOT | TEST_VMSTATE_PROG_MAIN | TEST_VMSTATE_STACKS) #define $test_vm_state_normal(p)$ test_vm_state((p), TEST_VMSTATE_NOT_RUNNING | TEST_VMSTATE_NOT_INTERRUPTED | TEST_VMSTATE_PROG_MAIN | TEST_VMSTATE_STACKS) /* ¬TEST_VMSTATE_ENV_ROOT */ void test_vm_state(char *prefix, int flags) char $msg[TEST_BUFSIZE] = \{0\};$ if $(flags \& TEST_VMSTATE_RUNNING) tap_ok(Running, tmsqf("(==_\Running__1)"));$ else $tap_ok(\neg Running, tmsqf("(==_Running_0)"));$ if (flags & TEST_VMSTATE_INTERRUPTED) tap_ok(Interrupt, tmsqf("(==|Interrupt|1)")); else $tap_ok(\neg Interrupt, tmsqf("(==_\ll Interrupt_\ll 0)"));$ if $(flags \& TEST_VMSTATE_VMS) \ tap_ok(null_p(VMS), tmsgf("(null?_\UVMS)"));$ if $(flags \& TEST_VMSTATE_CTS) tap_ok(null_p(CTS), tmsgf("(null?_\CTS)"));$ if $(flags \& TEST_VMSTATE_RTS)$ $tap_ok(RTSp \equiv -1, tmsgf("(== LRTSp_L-1)"));$ if $(flags \& TEST_VMSTATE_ENV_ROOT) tap_ok(Env \equiv Root, tmsqf("(==|Env|_Root)"));$ if (flags & TEST_VMSTATE_PROG_MAIN) { $tap_ok(Prog \equiv Prog_Main, tmsqf("Prog_Main_is_returned_to"));$ $tap_ok(Ip \equiv vector_length(Prog_Main) - 1, tmsqf("Prog_Main_is_completed"));$ } /* TODO? Others: root unchanged; */

```
255. int test\_count\_free\_list(void) {
    int r = 0;
    cell c = Cells\_Free;
    if (\neg Cells\_Poolsize) return 0;
    while (\neg null\_p(c)) {
        r++;
        c = cdr(c);
    }
    return r;
}
```

256. Utilities: Unit Tests. This is the very boring process of laboriously checking that each function or otherwise segregable unit of code does what it says on the tin. For want of a better model to follow I've taken inspiration from Mike Bland's article "Goto Fail, Heartbleed, and Unit Testing Culture" describing how he created unit tests for the major OpenSSL vulnerabilities known as "goto fail" and "Heartbleed". The article itself is behind some sort of Google wall but Martin Fowler has reproduced it at https://martinfowler.com/articles/testing-culture.html.

```
\langle t/llt.h 256 \rangle \equiv
#ifndef LLT_H
#define LLT_H
  (Unit test fixture header 257)
  typedef struct llt_Fixture llt_Fixture;
                                                /* user-defined */
  typedef void (*llt_thunk)(llt_Fixture *);
  typedef boolean (*llt_case)(llt_Fixture *);
  typedef llt_buffer *(*llt_fixture)(void);
  extern llt_fixture Test_Fixtures[];
                                         /* user-defined */
\#define fmsgf(...)test\_msgf(buf, fix.name, __VA_ARGS__)
\#define fpmsgf(...)test\_msgf (buf, fix \neg name, \_\_VA\_ARGS\_\_)
  boolean llt_main(size_t, llt_Fixture *);
  llt\_buffer * llt\_prepare(void);
#endif
            /* LLT_H */
```

257. Unit test fixtures are defiend in a llt_Fixture structure which is only declared in this header; it is up to each unit test to implement its own llt_Fixture with this common header.

```
\langle \text{ Unit test fixture header 257} \rangle \equiv \\ \# \text{define LLT_FIXTURE_HEADER} \\ \quad \text{char } *name; \\ \quad \text{char } *suffix; \\ \quad \text{int } id; \\ \quad \text{llt_thunk } prepare; \\ \quad \text{llt_thunk } act; \\ \quad \text{llt_case } test; \\ \quad \text{llt_thunk } destroy; \\ \quad \text{boolean } skip\_gc\_p \qquad /* \text{ no semicolon } */
```

This code is used in section 256.

258. The vast majority (all, so far) of unit tests follow the same simple structure. There are plans for more interactive tests but they aren't necessary yet.

```
\langle Unit test header 258 \rangle \equiv #define LL_TEST #include "lossless.h" #include "llt.h" This code is used in sections 268, 287, 300, 333, 343, 358, 380, and 443.
```

```
259. \langle \text{Unit test body } 259 \rangle \equiv
  int main(int argcll_unused, char **argvll_unused)
     llt_buffer *suite;
     if (argc > 1) {
       printf("usage: \_\%s", argv[0]);
       return EXIT_FAILURE;
#ifndef LLT_NOINIT
     vm_{-}init();
\#\mathbf{endif}
     suite = llt\_prepare();
     llt_main(suite→len, (llt_Fixture *) suite→data);
     free(suite);
     tap\_plan(0);
  }
See also sections 260 and 263.
This code is used in sections 268, 287, 300, 333, 343, 358, 380, and 443.
260. \langle \text{Unit test body } 259 \rangle + \equiv
  boolean llt_main(size_t count, llt_Fixture *suite)
     int i:
     int d, f0, f1;
     boolean all, ok;
     char buf[TEST\_BUFSIZE] = \{0\}, *name;
     all = btrue;
     for (i = 0; i < (int) count; i++) {

  ok = suite[i].test(suite + i);
  if (suite[i].destroy) suite[i].destroy(suite + i);
  suite[i].name = name;
This code is used in section 260.
```

262. This is substantially the same as the previous section except that after the fixture is prepared *cons* is called repeatedly to waste cells before the fixture's action is taken.

```
\langle Repeat the fixture with garbage collection _{262}\rangle \equiv
  int j, k;
  for (j = d; j \ge 0; j --) {
     sprintf(buf, \verb""%s:\_trigger\_gc\_at\_%d\_free\_cells", name, j);
     name = (\mathbf{char} \ *) \ suite[i].name;
     suite[i].name = buf;
     if (suite[i].prepare) suite[i].prepare(suite + i);
     d = test\_count\_free\_list();
     for (k = 0; k < d - j; k++) cons(NIL, NIL);
     suite[i].act(suite + i);
     ok = suite[i].test(suite + i) \land ok;
     if (suite[i].destroy) suite[i].destroy(suite + i);
     suite[i].name = name;
  if (suite[i].suffix) snprintf(buf, TEST\_BUFSIZE, "%s_\( (%s) ", name, suite[i].suffix);
  else snprintf(buf, TEST_BUFSIZE, "%s", name);
  suite[i].name = buf;
This code is used in section 260.
263. \langle \text{Unit test body } 259 \rangle + \equiv
  llt_buffer *llt_prepare(void)
     llt_fixture *t;
     llt_buffer *f, *r;
     size_t old;
     int i;
     r = llt\_alloc(0, \mathbf{llt\_Fixture});
     for (t = Test\_Fixtures; *t \neq \Lambda; t++) {
        f = (*t)();
        old = r \neg len;
        llt\_grow(r, f \rightarrow len);
        bcopy(f \rightarrow data, ((\mathbf{llt\_Fixture} *) r \rightarrow data) + old, f \rightarrow len * f \rightarrow size);
        free(f);
     for (i = 0; i < (int) \ r \rightarrow len; i ++) \ ((llt_Fixture *) \ r \rightarrow data)[i].id = i;
     return r;
  }
```

264. Utilities: Miscellaneous. Other bits and pieces only of interest to the tests.

265. Old tests. Some early tests were churned out while the test system itself was in flux. These tests will be incorporated into the unit testing framework eventually but until that is carried out they need a legacy test script wrapper.

```
#define test_copy_env() Env
#define test\_compare\_env(o) ((o) \equiv Env)
#define test\_is\_env(o, e) ((o) \equiv (e))
\langle Old test executable wrapper 265\rangle \equiv
\#define LL_TEST 1
#include "lossless.h"
  void test_main(void);
  int main(int argcll_unused, char **argvll_unused)
     volatile boolean first = btrue;
     vm_-init();
    \mathbf{if} \ (\mathit{argc} > 1) \ \mathbf{error} \ (\mathtt{ERR\_ARITY\_EXTRA}, \mathtt{NIL});
     vm_prepare();
    if (\neg first) {
       printf("Bail_uout!_uUnhandled_uexception_uin_test\n");
       return EXIT_FAILURE;
    first = bfalse;
     test_main();
     tap_plan(0);
    return EXIT_SUCCESS;
```

This code is used in sections 472, 484, 493, 502, 509, and 516.

266. Sanity Test. This seemingly pointless test achieves two goals: the test harness can run it first and can abort the entire test suite if it fails, and it provides a simple demonstration of how individual test scripts interact with the harness, without obscuring it with the more complicated unit test framework below.

LossLess Programming Environment

108

Heap Allocation. The first units we test are the memory allocators because I've already found embarrassing bugs there proving that even that "obvious" code needs manual verification. To do that we will need to be able to make reallocarray fail without actually exhausting the system's memory. A global counter is decremented each time this variant is called and returns Λ if it reaches zero.

This method of implementing unit tests has us pose 5 questions:

What is the contract fulfilled by the code under test?

new_cells_segment performs 3, or 5 if each allocation is counted seperately, actions: Enlarge each of CAR, CDR & TAG in turn, checking for out-of-memory for each; zero-out the newly-allocated range of memory; update the global counters Cells_Poolsize & Cells_Segment.

There is no return value but either the heap will have been enlarged or one of 3 (mostly identical) errors will have been raised.

What preconditions are required, and how are they enforced?

Cells_Segment describes how much the pool will grow by. If Cells_Poolsize is 0 the three pointers must be Λ otherwise they each point to an area of allocated memory Cells_Poolsize elements wide. There is no explicit enforcement.

What postconditions are guaranteed?

IFF there was an allocation error for any of the 3 pools, the pointer under question will not have changed but those reallocated before it may have. Cells_Poolsize & Cells_Segment will be unchanged. Any newlyallocated memory should not be considered available

Otherwise CAR, CDR & TAG will point to still-valid memory but possibly at the same address.

The newly allocated memory will have been zerod.

Cells_Poolsize & Cells_Segment will have been enlarged.

new_cells_segment also guarantees that previously-allocated data will not have changed but it's safe for now to rely on reallocarray getting that right.

What example inputs trigger different behaviors?

Chiefly there are two classes of inputs, whether or not Cells_Poolsize is 0, and whether allocation succeeds for each of the 3 attempts.

What set of tests will trigger each behavior and validate each guarantee?

Eight tests, four starting from no heap and four from a heap with data in it. One for success and one for each potentially failed allocation.

268. This unit test relies on the VM being uninitialised so that it can safely switch out the heap pointers. The $save_CAR$, $save_CDR$ & $save_TAG$ pointers in the fixture are convenience pointers into heap copy.

```
\langle t/cell-heap.c 268 \rangle \equiv

```

300. Garbage Collector. There are three parts to the garbage collector, each building on the last. The inner-most component is *mark* which searches the heap for any data which are in use.

- 1. What is the contract fulfilled by the code under test?
- 2. What preconditions are required, and how are they enforced?
- 3. What postconditions are guaranteed?

Given a **cell**, it and any objects it refers to—recursively, including internal components of atoms—will have their mark flag raised. No other objects will be affected and no other changes will be made to the objects which are. The global constants (specials) are ignored.

mark's main complication is that it's a linear implementation of a recursive algorithm. It can't use any of the real stacks to keep track of the recursion so it uses the individual cells its scanning as an impromptu stack. This heap mutation needs to have no visible external effect despite mutating every **cell** that's considered.

4. What example inputs trigger different behaviors?

Global constants and cells already marked vs. unmarked cells. Obviously different objects will be marked in their own way.

Constants aside, the different types of object come in one of 5 categories: pairs, vectors, atomic pairs, atomic lists (the car is opaque) and pure atoms (which are entirely opaque). These are referred to as P, V, A & L respectively.

5. What set of tests will trigger each behavior and validate each guarantee?

A test for each type of object—P, V, A & L as well as globals—created without any nesting and one for each recursive combination up to a depth of 3.

```
\langle t/gc-mark.c 300 \rangle \equiv
  (Unit test header 258)

         and 332.
This code is used in section 300.
302. Of course after the mark phase of garbage collection live objects have been changed because that's
the whole point so serialising the post-mark object as-is wouldn't work. Instead the flag is (recursively)
lowered first reverting the only change that mark should have made.
\langle Unit test: garbage collector mark 301\rangle + \equiv

333. Sweep.

What is the contract fulfilled by the code under test?

All cells which are marked will become unmarked and otherwise unchanged. All other cells will be on the free list (in an insignificant order). The size of the free list will be returned.

What preconditions are required, and how are they enforced?

The pool need not have been initialised in which case the free list and return value are NIL and 0 respectively. Live objects should be already marked for which we define llt_GC_Sweep_mark_m which also counts the size of the object being marked.

What postconditions are quaranteed?

The car content of a cell put into the free list is unchanged but this doesn't matter.

What example inputs trigger different behaviors?

Exactly 2: The size of the pool and the set of marked cells.

What set of tests will trigger each behavior and validate each guarantee?

There are three tests. The simplest is to verify that sweep is effectively a no-op when there is no pool. The other two both prepare a dud object which should be returned to the free list and test whether sweep works correctly both with and without a live object.

```
\langle t/gc-sweep.c 333 \rangle \equiv
  (Unit test header 258)
  struct llt_Fixture {
     LLT_FIXTURE_HEADER;
     boolean preinit_p;

342. \( \text{Unit test: garbage collector } sweep 334 \rightarrow + \equiv \text{llt_buffer } *llt_GC_Sweep_Used_Pool(\text{void}) \\ \{ \quad llt_buffer *r = llt_alloc(1, llt_Fixture); \quad llt_GC_Sweep_fix((llt_Fixture *) r¬data, __func__); \quad ((llt_Fixture *) r¬data)¬prepare = llt_GC_Sweep_Used_Pool_prepare; \quad return r; \) \}
```

343. Vectors.

1. What is the contract fulfilled by the code under test?

vector objects which are not live (pointed at by something in ROOTS) will have their tag changed to TAG_NONE and their cdr née offset changed to a pointer in the free list, as will all their contents.

Live *vectors* cell pointer, length and contents are unchanged. The offset will be reduced by the (full) size of any unused *vectors* prior to it in VECTOR.

The number of free cells in VECTOR is returned.

2. What preconditions are required, and how are they enforced?

Used vectors must be pointed to from something in ROOTS. They will be pushed into VMS.

The linear nature of $vector_new$ is taken advantage of to create the holes in the VECTOR buffer that $gc_vectors$ must defragment.

All other aspects of the garbage collector are assumed to work correctly.

3. What postconditions are guaranteed?

The VM is fully reset after each test so that they begin with VECTOR in a clean state.

4. What example inputs trigger different behaviors?

The only things to affect the way *vector* garbage collection works is whether or not each vector is live and where they exist in memory in relation to one another, ie. whether unused vectors will leave holes in VECTOR after collection.

5. What set of tests will trigger each behavior and validate each guarantee?

The VECTOR buffer will be packed with live/unused objects in various arrangements.

```
#define LLT_GC_VECTOR__SIZE "2718281828459"
#define LLT_GC_VECTOR__SHAPE "GNS"
\langle t/gc\text{-vector.c} \quad 343 \rangle \equiv
  (Unit test header 258)
  struct llt_Fixture {
     LLT_FIXTURE_HEADER;
     char *pattern;
     int ret_{-}val;
     size_t \ safe_size;
     llt_buffer *cell_buf;
                                /* refs of live vectors */
     llt_buffer *offset_buf;
                                  /* original live offsets */
                                 /* serialised live vectors */
     llt_buffer *safe_buf;
                                   /* refs of unsafe vectors */
     llt_buffer *unsafe_buf;
  (Unit test body 259)
  \langle \text{Unit test: garbage collector } gc\_vector \ 344 \rangle
  llt_fixture Test_Fixtures[] = {
       llt\_GC\_Vector\_All, \Lambda
  };
```

These tests are highly repetetive so the *vectors* defined by the fixture are created programmatically according to the pattern in fix-pattern which is a simple language of L & U characters.

Each vector is created by taking a character from the pattern and LLT_GC_VECTOR__SIZE in turn to decide on the size of the vector and whether it is live or unused. LLT_GC_VECTOR__SHAPE is then cycled through to populate each *vector* with a variety of data.

Live vectors are pushed onto VMS to keep them safe from collection. Vectors which will be considered unused are pushed onto CTS to keep them safe from collection while the fixture is being prepared.

```
\langle \text{Unit test: garbage collector } gc\_vector \ 344 \rangle \equiv
     /* There are too many one-letter variables in this function which then get reused */
  void llt_GC_Vector_prepare(llt_Fixture *fix)
     cell g, v;
     char buf[TEST_BUFSIZE], *p, *s, *t;

369. Setting a variable in an *environment* is really two mostly different processes depending on whether the variable is being created anew in the *environment* or replacing one, which must be first found and removed. Their tests are named **define** and **set**, respectively, to match the **LossLess** operators which call them.

```
TODO: non-empty environment.

TODO: variable in different parts of the layer (head, mid, tail).

TODO: verify that the old binding is removed.

(Unit test: environment objects 359) +=

void llt_Environments__Set_act(llt_Fixture *fix)

{
    fix¬had_ex_p = bfalse;
    if (¬setjmp(Goto_Error)) env_set(Env, fix¬sym_mpf[0], fix¬sym_mpf[1], fix¬new_p);
    else fix¬had_ex_p = btrue;
}
```

370. Regardless of the route taken there are only two possible outcomes: the variable gets set or an error is raised.

```
\langle Unit test: environment objects 359\rangle + \equiv
  boolean llt_Environments__Set_test(llt_Fixture *fix)
     char buf[TEST_BUFSIZE] = \{0\};
     boolean ok;
     cell found;
     if (fix→want_ex_p) {
       ok = tap\_ok(fix \neg had\_ex\_p, fpmsgf("an\_error\_was\_raised"));
       if (fix \rightarrow new_p) {
          tap\_again(ok, ex\_id(Acc) \equiv Sym\_ERR\_BOUND \land ex\_detail(Acc) \equiv fix \rightarrow sym\_mpf[0],
               fpmsgf("the | error | is | bound | marco"));
       else {

    fix[5].want_ex_p = btrue;
    fix[5].expect = UNDEFINED;
    return r;
```

372. Lifting stack items into an environment has many moving parts so we return to more formally deriving its test cases.

1. What is the contract fulfilled by the code under test?

Expects an environment E_0 and formals, which is a symbol, NIL or a possibly-dotted list of symbols or NIL. Returns an extension of that environment E_1 .

Pops a stack item for every element of the list of formals (acting as though a dotted list were proper and a plain symbol were a list of 1 symbol). If the formal item is not NIL then the popped item is included in E_1 , named by the formal. E_0 remains unchanged.

Allocates storage and may call garbage collection.

2. What preconditions are required, and how are they enforced?

env_lift_stack does not validate its inputs or protect its arguments so the stack must be populated correctly and the arguments saved from garbage collection.

3. What postconditions are guaranteed?

An environment will always be returned. The stack will have been cleared of the arguments.

4. What example inputs trigger different behaviors?

Only the formals has any impact on operation. In particular whether it is NIL, a symbol or a list and, if a list, whether it contains NILs or is improper.

5. What set of tests will trigger each behavior and validate each guarantee?

A list of formals of lengths 0, 1, 2 & 3 with variants with and without NIL. Lengths 1 and 2 additionally test a lone symbol and an improper list.

```

441. OP_SYNTAX.

442. OP_VOV.

443. Compiler.

The compiler generates bytecode from s-expressions, or raises a syntax or arity error. These tests verify that bytecode is generated when it should be not that the generated bytecode correctly implements the operator in question. This validation is performed by later tests of the integration between the compiler and the interpreter.

Each test fixture (if the compilation is expected to succeed) includes a C-string representation of the bytecode it is expected to generate which is compared with the bytecode's written representation.

450. $compile_eval$.

What is the contract fulfilled by the code under test?

A list who's first expression is the symbol eval is passed as an argument to compile, which will pass control to compile_eval. An error is raised if other than one or two more expressions is in the list, otherwise it's compiled and the bytecode returned. compile takes no action to preserve its argument from the garbage collector. The argument values are not validated at this compile-time.

What preconditions are required, and how are they enforced?

A C-string representing the expression to be compiled is read in. The majority if the VM state is ignored.

What postconditions are quaranteed?

The tests that expect an error to be raised will see that error in Acc and compile will not return. CTS may be changed but it can be ignored.

When compilation was a success the compilation result will be returned and CTS will be empty.

What example inputs trigger different behaviors?

The number of arguments to **eval** and their form (specifically, what each compiles to).

What set of tests will trigger each behavior and validate each guarantee?

Four tests of 0, 1, 2 and 3 constant-value arguments validate that the VM is unchanged when compilation is a success or otherwise changed correctly.

The one-expression case is repeated three times with different types of expression to validate that the evaluating expression compiles.

These tests are duplicated again for the two-expression case; each test three times with the same types of different expression in the second position for a total of 9 two-expression tests.

TODO: explain these macros.

457. $compile_lambda$.

1. What is the contract fulfilled by the code under test?

An error is raised if there is not at least one argument, the remaining arguments (the body) are not a proper list, or the first argument isn't in the form of **lambda** formals, ie. NIL, a symbol or a possibly improper list of #fs or $unique\ symbols$.

Otherwise the form is accepted and the *formals* and *body* are compiled into bytecode which will build an applicative closure.

- 2. What preconditions are required, and how are they enforced?
- 3. What postconditions are guaranteed?

As with other compilers the virtual machine's dynamic state apart from the heap has no effect on the result and will be unchanged under all circumstances.

When bytecode is compiled it will reference the new applicative's formals list directly and this compiled list will not share any mutable references with the source s-expression.

4. What example inputs trigger different behaviors?

Whether the body compiles or not depends on whether it's a well-formed list or not. What the expression compiles to is affected by what the list contains. This is a moot point because it's done by compile_list which is tested elsewhere and there's no value in repeating its tests. This test will only concentrate on demonstrating that an improper list is a syntax error.

Otherwise well formed vs. invalid formals including formals which repeat symbols will exercise each code path of interest.

5. What set of tests will trigger each behavior and validate each guarantee?

Broadly speaking they can be grouped into three categories: Failure when the formals are invalid, failure when the body is improper and successful compilation of valid forms. Failures:

These tests all work by dynamically constructing a C-string of LossLess code. That string is formed when the fixture is defined based on short strings of S, D, I and O which expand to a symbol, a duplicate (ie. re-use a symbol used previously), an ignored argument and object respectively. Object means to put something invalid in the formals, in this case #t is used which has the added advantage of ensuring that #t doesn't accidentally become permitted and allow untold end-user frustration.

Two fixtures are defined for each test of the formals (except formals of NIL when that makes no sense) with the latter of the pair creating an improper formals list (a plain symbol and #f are tested this way).

```
⟨ Unit test: Compiler 444⟩ +≡
void llt_Compiler_Lambda_prepare(llt_Fixture *fix)
{
    llt_Compiler_prepare(fix);
    car(fix¬src_val) = env_search(Root, sym("lambda"));
}
```

211

This unit test must check that no mutable cell from the formals in the expression is included in the bytecode. The method of testing relies on the compiler not modifying the source expression rather than attempt to store it beforehand.

```
\langle \text{Unit test: Compiler 444} \rangle + \equiv
  boolean llt_Compiler__Lambda_test(llt_Fixture *fix)
     char buf[TEST_BUFSIZE] = \{0\};

This code is used in section 465.

465. The longest source string created by any of these test cases is (lambda_(#f_#f_..#f)) which is 21 bytes including the terminating zero terminator. To avoid excessive allocation of tiny buffers 100 bytes is allocated for each pair of fixtures giving each 25 bytes to hold the source string and a shorter representation to name the test for display. If test cases are defined involving longer expressions then the length of this buffer will need to be increased (or switched to dynamic allocation).

```

```

471. I/O.

472. Pair Integration. With the basic building blocks' interactions tested we arrive at the critical integration between the compiler and the interpreter.

Calling the following tests integration tests may be thought of as a bit of a misnomer; if so consider them unit tests of the integration tests which are to follow in pure LossLess code.

Starting with pairs tests that cons, car, cdr, null?, pair?, set-car! & set-cdr! return their result and don't do anything strange. This code is extremely boring and repetetive.

```
\langle t/pair.c 472 \rangle \equiv
  (Old test executable wrapper 265)
  void test_main(void)
    boolean ok, okok;
                                        /* t is not saved from destruction */
    cell marco, polo, t, water;
    \mathbf{char} * prefix = \Lambda;
    char msg[TEST\_BUFSIZE] = \{0\};
    marco = sym("marco?");
    polo = sym("polo!");
    water = sym("fish_lout_lof_lwater!");
     ⟨ Test integrating cons 473⟩
     (Test integrating car 474)
     (Test integrating cdr 475)
     (Test integrating null? 476)
     Test integrating pair? 479
     \langle \text{ Test integrating set-car! } 482 \rangle
     (Test integrating set-cdr! 483)
  }
```

473. These tests could perhaps be made more thorough but I'm not sure what it would achieve. Testing the non-mutating calls is basically the same: Prepare & interpret code that will call the operator and then test that the result is correct and that internal state is (not) changed as expected.

```
\langle \text{ Test integrating cons } 473 \rangle \equiv

  tap\_again(okok, symbol\_p(cdr(Tmp\_Test)) \land cdr(Tmp\_Test) \equiv polo, tmsgf("(eq?_i(cdr_iT)_i'polo!)"));
This code is used in section 472.
```

484. Integrating eval. Although useful to write, and they weeded out some dumb bugs, the real difficulty is in ensuring the correct *environment* is in place at the right time.

We'll skip **error** for now and start with **eval**. Again this test isn't thorough but I think it's good enough for now. The important tests are that the arguments to **eval** are evaluated in the compile-time environment in which the **eval** is located, and that the program which the first argument evaluates to is itself evaluated in the environment the second argument evaluates to.

485. The first test of **eval** calls into it without needing to look up any of its arguments. The program to be evaluated calls *test!probe* and its result is examined. First evaluating in the current environment which is here *Root*.

```
 \begin{array}{l} \langle \operatorname{Test\ integrating\ eval\ } 485 \rangle \equiv \\ vm\_reset(); \\ Acc = read\_cstring((prefix = "(eval_{\square}'(test!probe))")); \\ interpret(); \\ t = assoc\_value(Acc, sym("Env")); \\ tap\_ok(environment\_p(t), tmsgf("(environment?_{\square}(assoc\_value_{\square}T_{\square}'Env))")); \\ tap\_ok(t \equiv Root, tmsgf("(eq?_{\square}(assoc\_value_{\square}T_{\square}'Env)_{\square}Root)")); \\ /*\ TODO: \text{ Is it worth testing that } Acc \equiv Prog \equiv [\text{ OP\_TEST\_PROBE OP\_RETURN }]? */test\_vm\_state\_full(prefix); \\ \text{See also sections } 486, 487, \text{ and } 488. \\ \text{This code is used in section } 484. \\ \end{array}
```

486. And then testing with a second argument of an artificially-constructed environment.

The probing symbol is given a different name to shield against it being found in *Root* and fooling the tests into passing.

```
 \begin{array}{l} \langle \operatorname{Test\ integrating\ eval\ } 485 \rangle + \equiv \\ vm\_reset(); \\ Tmp\_Test = env\_empty(); \\ env\_set(Tmp\_Test, sym("alt-test!probe"), env\_search(Root, sym("test!probe")), TRUE); \\ Acc = read\_cstring((prefix = "(eval_{\square}'(alt-test!probe)_{\square}E)")); \\ cddr(Acc) = cons(Tmp\_Test, NIL); \\ interpret(); \\ t = assoc\_value(Acc, sym("Env")); \\ tap\_ok(environment\_p(t), tmsgf("(environment?_{\square}(assoc-value_{\square}T_{\square}'Env))")); \\ tap\_ok(t \equiv Tmp\_Test, tmsgf("(eq?_{\square}(assoc-value_{\square}T_{\square}'Env)_{\square}E)")); \\ test\_vm\_state\_full(prefix); \\ \end{array}
```

- **487.** Testing that **eval**'s arguments are evaluated in the correct *environment* is a little more difficult. The *environment* with variables to supply **eval**'s arguments is constructed. These are the program source and another artificial *environment* which the program should be evaluated in.
- t, m & p are protected throughout as they are only links to somewhere in the outer *environment* which is protected by Tmp_Test .

```
 \begin{tabular}{ll} $\langle {\rm Test\ integrating\ eval\ 485} \rangle + \equiv \\ $Tmp\_Test = env\_empty(); & /*\ outer\ environment\ */\\ env\_set(Tmp\_Test, sym("eval"), env\_search(Root, sym("eval")), {\rm TRUE});\\ env\_set(Tmp\_Test, sym("alt-test!probe"), env\_search(Root, sym("error")), {\rm TRUE});\\ $t = read\_cstring("(alt-test!probe_\_'oops)"); & /*\ program; oops\ in\ case\ we\ end\ up\ in\ error\ */\\ env\_set(Tmp\_Test, sym("testing-program"), t, {\rm TRUE});\\ $m = env\_empty(); & /*\ evaluation\ environment\ */\\ env\_set(Tmp\_Test, sym("testing-environment"), m, {\rm TRUE});\\ env\_set(m, sym("alt-test!probe"), env\_search(Root, sym("test!probe")), {\rm TRUE});\\ env\_set(m, sym("testing-environment"), env\_empty(), {\rm TRUE});\\ $p = read\_cstring("(error_\surong-program"), p, {\rm TRUE});\\ env\_set(m, sym("testing-program"), p, {\rm TRUE});\\ \env\_set(m, sym("testing-program"), p, {\rm TRUE});\\ \env\_se
```

488. eval is then called in the newly-constructed *environment* by putting it in *Env* before calling *interpret*, mimicking what *frame_push* would do when entering the closure the *environment* represents.

```
 \begin{array}{l} \langle \, {\rm Test \; integrating \; eval \; 485} \, \rangle \, + \equiv \\ vm\_reset(); \\ prefix = "(eval\_testing\_program\_testing\_environment)"; \\ Acc = read\_cstring(prefix); \\ Env = Tmp\_Test; \\ interpret(); \\ t = assoc\_value(Acc, sym("Env")); \\ tap\_ok(environment\_p(t), tmsgf("(environment?_{\sqcup}(assoc\_value\_T_{\sqcup}'Env))")); \\ tap\_ok(t \equiv m, tmsgf("(eq?_{\sqcup}(assoc\_value\_T_{\sqcup}'Env)_{\sqcup}E)")); \\ test\_integrate\_eval\_unchanged(prefix, Tmp\_Test, m); \\ test\_vm\_state\_normal(prefix); \\ tap\_ok(Env \equiv Tmp\_Test, tmsgf("(unchanged?_{\sqcup}Env)")); \end{array}
```

489. Neither of the two environments should be changed at all. That is *inner* should have exactly alttest!probe, testing-environment & testing-program, *outer* should have the same symbols with the different values as above and also eval.

```

```

```
492. \langle Test the inner environment when testing eval 492\rangle \equiv oki = tap\_ok(environment\_p(inner), tmsgf("(environment?_linner)")); tap\_ok(env\_root\_p(inner), tmsgf("(environment.is-root?_linner)")); if (oki) { iprobe = env\_search(Root, sym("test!probe")); t = env\_layer(inner); TEST_EVAL_FIND if (\neg undefined\_p(fprog)) oki = list\_p(fprog, FALSE, \&t) \land int\_value(t) \equiv 2; } tap\_again(oki, \neg fmore \land undefined\_p(feval) \land fprobe \equiv iprobe \land env\_empty\_p(fenv), tmsgf("inner\_environment\_is\_unchanged")); This code is used in section 490.
```

493. Conditional Integration. Before testing conditional interaction with *environments* it's reassuring to know that **if**'s syntax works the way that's expected of it, namely that when only the conequent is provided without an alternate it is as though the alternate was the value VOID, and that a call to it has no unexpected side-effects.

```
\langle t/if.c \quad 493 \rangle \equiv
  (Old test executable wrapper 265)
  void test_main(void)
    cell fcorrect, tcorrect, fwrong, twrong;
    cell talt, tcons, tq;
    cell marco, polo, t;
    \mathbf{char} * prefix = \Lambda;
    char msg[TEST_BUFSIZE] = \{0\};
    fcorrect = sym("correct-false");
    fwrong = sym("wrong-false");
    tcorrect = sym("correct-true");
    twrong = sym("wrong-true");
    talt = sym("test-alternate");
    tcons = sym("test-consequent");
    tq = sym("test-query");
    marco = sym("marco?");
    polo = sym("polo!");
     \langle \text{Sanity test if's syntax 494} \rangle
    ⟨ Test integrating if 498⟩
  }
```

494. Four tests make sure **if**'s arguments work as advertised. These are the only tests of the 2-argument form of **if**.

```
(if #t 'polo!) \Rightarrow polo!:
\langle \text{Sanity test if's syntax 494} \rangle \equiv
  vm\_reset();
  t = cons(synquote\_new(polo), NIL);
  t = cons(TRUE, t);
  Acc = cons(sym("if"), t);
  prefix = "(if_{\sqcup}#t_{\sqcup}'polo!)";
  interpret();
  tap\_ok(symbol\_p(Acc) \land Acc \equiv polo, tmsgf("symbol?"));
  test\_vm\_state\_full(prefix);
See also sections 495, 496, and 497.
This code is used in section 493.
       (if #f 'marco?) \Rightarrow VOID:
\langle \text{Sanity test if's syntax 494} \rangle + \equiv
  vm\_reset();
  t = cons(synquote\_new(marco), NIL);
  t = cons(FALSE, t);
  Acc = cons(sym("if"), t);
  prefix = "(if_{\sqcup}#f_{\sqcup}'marco?)";
  interpret();
  tap\_ok(void\_p(Acc), tmsgf("void?"));
  test\_vm\_state\_full(prefix);
```

```
496.
       (if #t 'marco? 'polo!) ⇒ marco?:
\langle \text{Sanity test if's syntax 494} \rangle + \equiv
  vm\_reset();
  t = cons(synquote\_new(polo), NIL);
  t = cons(synquote\_new(marco), t);
  t = cons(TRUE, t);
  Acc = cons(sym("if"), t);
  prefix = "(if u#t u'marco? u'polo!)";
  interpret();
  tap\_ok(symbol\_p(Acc) \land Acc \equiv marco, tmsgf("symbol?"));
  test\_vm\_state\_full(prefix);
497. (if #f 'marco? 'polo!) \Rightarrow polo!:
\langle \text{Sanity test if's syntax 494} \rangle + \equiv
  vm\_reset();
  t = cons(synquote\_new(polo), NIL);
  t = cons(synquote\_new(marco), t);
  t = cons(FALSE, t);
  Acc = cons(sym("if"), t);
  prefix = "(if_{\sqcup}#f_{\sqcup}'marco?_{\sqcup}'polo!)";
  interpret();
  tap\_ok(symbol\_p(Acc) \land Acc \equiv polo, tmsgf("symbol?"));
  test\_vm\_state\_full(prefix);
```

498. To confirm that **if**'s arguments are evaluated in the correct *environment Root* is replaced with a duplicate and invalid variants of the symbols inserted into it. This is then extended into a new *environment* with the desired version of the four symbols **if**, test-query, test-consequent and test-alternate.

```
\langle \text{ Test integrating if } 498 \rangle \equiv
  t = env\_layer(Tmp\_Test = Root);
  Root = env_empty();
  for ( ; \neg null\_p(t); t = cdr(t))
     if (caar(t) \neq sym("if")) env\_set(Root, caar(t), cadar(t), btrue);
  env_set(Root, sym("if"), env_search(Tmp_Test, sym("error")), btrue);
  env\_set(Root, talt, fwrong, btrue);
  env_set(Root, tcons, twrong, btrue);
  env\_set(Root, tq, VOID, btrue);
  Env = env\_extend(Root);
  env_set(Env, sym("if"), env_search(Tmp_Test, sym("if")), btrue);
  env_set(Env, talt, fcorrect, btrue);
  env\_set(Env, tcons, tcorrect, btrue);
  env\_set(Env, tq, VOID, btrue);
See also sections 499, 500, and 501.
This code is used in section 493.
```

499. The test is performed with test-query resolving to #f & #t. \langle Test integrating **if** 498 \rangle + \equiv $vm_reset();$ $env_set(Env, tq, \mathtt{FALSE}, bfalse);$ t = cons(talt, NIL);t = cons(tcons, t);t = cons(tq, t);Acc = cons(sym("if"), t); $prefix = "(let_{\sqcup}((query_{\sqcup}#f))_{\sqcup}(if_{\sqcup}query_{\sqcup}consequent_{\sqcup}alternate))";$ t = Env;interpret(); $tap_ok(symbol_p(Acc) \land Acc \equiv fcorrect, tmsgf("symbol?"));$ test_vm_state_normal(prefix); $tap_ok(Env \equiv t, tmsgf("(unchanged?_{\sqcup}Env)"));$ **500.** $\langle \text{ Test integrating if } 498 \rangle + \equiv$ $vm_reset();$ $env_set(Env, tq, TRUE, bfalse);$ t = cons(talt, NIL);t = cons(tcons, t);t = cons(tq, t);Acc = cons(sym("if"), t); $prefix = "(let_{\sqcup}((query_{\sqcup}\#t))_{\sqcup}(if_{\sqcup}query_{\sqcup}consequent_{\sqcup}alternate))";$ t = Env;interpret(); $tap_ok(symbol_p(Acc) \land Acc \equiv tcorrect, tmsqf("symbol?"));$ test_vm_state_normal(prefix); $tap_ok(Env \equiv t, tmsgf("(unchanged?_LEnv)"));$ 501. It is important that the real Root is restored at the end of these tests in order to perform any more

testing.

```
\langle \text{ Test integrating if } 498 \rangle + \equiv
   Root = Tmp\_Test;
```

502. Applicatives. Testing **lambda** here is mostly concerned with verifying that the correct environment is stored in the closure it creates and then extended when it is entered.

These tests (and **vov**, below) could be performed using higher-level testing and *current-environment* but a) there is no practically usable **LossLess** language yet and b) I have a feeling I may want to write deeper individual tests.

```
\langle Old test executable wrapper 265\rangle
  void test_main(void)
    boolean ok;
    cell ie, oe, len;
    cell t, m, p;
    \mathbf{cell}\ sn,\ si,\ sin,\ sinn,\ so,\ sout,\ soutn;
    char *prefix;
    char msg[\texttt{TEST\_BUFSIZE}] = \{0\};
       /* Although myriad these variables' scope is small and they are not used between the sections */
    sn = sym("n");
    si = sym("inner");
    sin = sym("in");
    sinn = sym("in-n");
    so = sym("outer");
    sout = sym("out");
    soutn = sym("out-n");
    ⟨Test calling lambda 503⟩
    (Test entering an applicative closure 504)
     \langle Applicative test passing an applicative 505\rangle
     (Applicative test passing an operative 506)
     (Applicative test returning an applicative 507)
    (Applicative test returning an operative 508)
```

This code is used in section 502.

 $test_vm_state_normal(prefix);$

505. Given that we can compile and enter an applicative closure, this test assures that we can correctly enter a closure that's passed as an argument to it. The expression being evaluated is: ((lambda₀ (L_1 . x0) (L_1 (test!probe₀))) (lambda₁ (T_0 . x1) (test!probe₁))) except that the same technique as the previous test compiles each expression in its own *environment*.

Entering the outer closure extends the *environment* E_0 to E_1 which will be contained in the probe result that's an argument to the inner closure.

Entering the inner closure extends its *environment* E_2 to E_3 .

```
#define TEST_ACA_INNER "(lambda_{\sqcup}(T_{\sqcup}._{\sqcup}x1)_{\sqcup}(test!probe))"
#define TEST_ACA_OUTER "(lambda_{\sqcup}(L_{\sqcup}._{\sqcup}x0)_{\sqcup}(L_{\sqcup}(test!probe)))"

```

507. Similar to applicatives which call into another closure are applicatives which return one. Starting with an *applicative*-returning-applicative (lambda (outer n) (lambda (inner n) (test!probe))).

This is a function which takes two arguments, outer and n and creates another function which closes over them and takes two of its own arguments, inner and n.

The test calls this by evaluating ((X 'out 'out-n) 'in 'in-n) with the above code inserted in the X position.

When the inner lambda is evaluating test!probe its local $environment\ E_2$ should be an extension of the dynamic $environment\ E_1$ that was created when entering the outer closure. E_1 should be an extension of the run-time $environment\ E_0$ when the closure was built.

```
#define TEST_ARA_INNER "(lambda_(inner_n)_(test!probe))"
#define TEST_ARA_BUILD "(lambda_(outer_n)_"TEST_ARA_INNER")"
#define TEST_ARA_PRINT TEST_ARA_BUILD
#define TEST_ARA_CALL "((LAMBDA_'out_'out-n)_'in_'in-n)"
\langle Applicative test returning an applicative 507\rangle
  Env = env\_extend(Root);
                                /* E_0 */
  Tmp\_Test = cons(test\_copy\_env(), NIL);
  Acc = read\_cstring(TEST\_ARA\_BUILD);

```

512. Calling an applicative inside an operative closure is no different from any other function call. An operative closure is entered with the result of lambda as an argument: ((VOV) (lambda x1 (test!probe))).

Operative's arguments are not evaluated so whether a **lambda** expression, variable lookup or whatever the operative evaluates its argument in the caller's *environment* then calls into it along with its own probe: ((vov (...) (cons ((eval (car A) E)) (test!probe))) (LAMBDA)).

The operative's compile-time *environment* E_0 is extended up entering it to E_1 . The run-time *environment* E_2 is extended when entering the callee's applicative and is passed to the operative.

```

514. Building applicatives and operatives within an operative requires extra care to evaluate code in the correct *environment*.

The environment E_1 that a returned applicative closes over, and will extend into E_2 when it's entered, is the local environment of the operative.

The outer operative evaluates its two arguments in its caller's *environment* E_0 , saving them in *outer* and n in turn, and then calls **lambda**.

```
#define TEST_ORA_INNER "(lambda_(inner_n)_(test!probe))"

This code is used in section 509.
```

515. Closing over an operative within an operative requires even more care that the correct environment is used so that the returned operative has access to its creator's local environment.

The creating operative extends the *environment* E_0 it closes over and this *environment* E_1 is then closed over by the returned operative. E_1 is extended upon entering the inner operative into *environment* E_2 .

The same run-time environment E_3 is passed as an argument to the each operative.

```

```

516. Exceptions. When an error occurs at run-time it has the option (unimplemented) to be handled at run-time but if it isn't then control returns to before the beginning of the main loop. Each time around the main loop, *interpret* begins by calling *vm_reset* but that explicitly *doesn't* change the *environment* to allow for run-time mutation and expects that well-behaved code will clear the stack correctly.

These exception tests enter a closure, which creates a stack frame, and call **error** within it. The tests then ensure that the *environment* and stack are ready to compute again.

There is no actual support for exception handlers so the interpreter will halt and jump back Goto_Begin.

```
\#define GOTO_FAIL "((lambda_\u00bdx_\u00bd(error_\u00bdfail)))"
